Chapter 1

GoTools Library

1.1 Introduction

The newest version of GoTools is available from <http://www.sintef.no/Geometry-Toolkits>.

GoTools is licensed under the [GNU General Public License](#)

GoTools is the group name of many interdependent C++ software modules developed by the geometry group at SINTEF ICT, Dept. of Applied Mathematics. GoTools software has been developed for a range of different applications in many different projects. However, a few key modules are used by almost all the others; these have been grouped together in [GoTools Core](#).

At the moment, the following GoTools modules are offered with GPL license:

- [GoTools Core](#). Parametric curves and surfaces including construction methods and operations on these entities
- [GoTools Parametrization](#). Parametrization of scattered data points
- [GoTools Implicitization](#). Approximating spline curves and surfaces by implicitly defined algebraic entities
- [GoTools Intersections](#). Intersection functionality involving spline curves and surfaces and computations of self intersections.
- [GoTools Igeslib](#). Read from and write to iges format.
- [GoTools Trivariate](#). Spline volumes and elementary volumes including some creation methods
- [GoTools Topology](#). Adjacency analysis for surface sets
- [GoTools CompositeModel](#). Representation of a surface set including topological entities and operations on a set of surfaces as one unit.
- [GoTools Trivariatemodel](#). A volume model including topology and some operations on the model
- [GoTools Viewlib](#). A utility viewer to visualize curves and surfaces
- [GoTools QualityModule](#). A set of tools to check the quality of CAD models
- [GoTools IsogeometricModel](#). A set of tools related to isogeometric analysis
- [GoTools LRsplines2D](#). LR spline surfaces

GoTools depends on:

- [SISL](#) (available with GPL license), SINTEF's spline library, for various spline related functionality,
- [TTL](#) (available with GPL license), a generic triangulation library,
- [newmat](#) (available with a permissive license), for various matrix operations.

For convenience, these libraries are included in the GPL version of GoTools.

1.2 Building GoTools

This GoTools package uses CMake to generate a Makefile (on Linux) or MS Visual Studio project file (on Windows).

For information on using CMake, see www.cmake.org.

As a Quick Start Guide, on Linux, make a build directory somewhere:

```
$ cd some_dir
$ mkdir build
$ cd build
$ ccmake <path_to_source_code>
```

Follow the instructions of 'ccmake' - the CMake "GUI". Then:

```
$ make
$ sudo make install
```

On Windows, add a new build folder somewhere. Start the CMake executable and fill in the paths to the source and build folders. When you run CMake, a Visual Studio project solution file will be generated in the build folder.

1.2.1 Compilers

The code uses certain features of the new C++ standard C++11, most notably the smart pointer `std::shared_ptr`. It has been tested on GCC 4.6.1 on Linux and Visual Studio 2010 on Windows.

A set of options to control the build can be accessed in CMake (names starting with `GoTools`). For example, you can turn on/off building the various modules by checking/unchecking `GoTools_COMPILE_MODULE_<modulename>`.

Also provided is the option `GoTools_USE_BOOST`. If this option is turned on, the building process uses `boost::shared_ptr` instead of `std::shared_ptr`. If a C++11 compliant compiler is not available, you may try this option and see if it works. Requires Boost: www.boost.org.

Chapter 2

GoTools CompositeModel

Contains tools for representing composite models.

This module depends on the following GoTools modules:

- GoTools Core
- GoTools Implicitization
- GoTools Intersection
- GoTools Parametrization
- GoTools Igeslib
- GoTools Topology

and the following modules external to GoTools:

- SISL (SINTEF)
- TTL (SINTEF)
- The newmat matrix library, which is freely available from www.robertnz.net.

SISL, TTL and newmat is included for convenience.

Chapter 3

GoTools example files

A number of example programs are created to illustrate the use of various GoTools functionality.

Example programs in gotools-core:

- [adapt_curve](#)
- [append_curve](#)
- [approx_curve](#)
- [approx_surface](#)
- [circle](#)
- [closestpoint_curve](#)
- [closestpoint_degenerate_sf](#)
- [closestpoint_surface](#)
- [cone](#)
- [const_param_curves](#)
- [coons_patch_gen](#)
- [cylinder](#)
- [ellipse](#)
- [interpol_curve_free](#)
- [interpol_curve_hermite](#)
- [linear_swept_surface](#)
- [project_curve](#)
- [rotational_swept_surface](#)
- [sphere](#)
- [surface_of_revolution](#)
- [torus](#)

The module trivariate has the following example programs:

- [coons_patch_volume_gen](#)
- [createCoonsVolume](#)
- [linear_swept_volume](#)
- [loft_volume_creator](#)
- [rotational_swept_volume](#)

The example programs related to `compositemodel`:

- [createSplitDisc](#)
- [createBlockStructuredDisc](#)
- [createVolumeBoundaries](#)
- [face2splineset](#)

The example programs in the `trivariatemodel` module are:

- [createMidShip](#)
- [mirrorAndLoft](#)
- [multiPatchSweep](#)

Chapter 4

GoTools Core

All GoTools modules depend on the `gtools-core` module. This module contains parametric curves and surfaces and functionality related to these entities. For clarity it is divided into four parts:

- *geometry* — contains classes and functionality for representing, storing and manipulating parameterized geometrical objects
- *utils* — contains general, low-level functionality
- *creators* — contains functionality for generating curves and surfaces by approximation, blending, etc.
- *tesselator* — contains functionality for making tessellations of geometry entities

4.1 Geometric Data Structures

The figure above shows the main geometry classes in GoTools.

All geometric objects are of type `GeomObject`. This class has a function `instanceType`, and by calling this function, it is possible to check the concrete type of a given object. A `GeomObject` is `Streamable`, which means that they can be written to and read from a stream (typically a file) in a uniform way. See [the g2-format documentation](#) for more information on this topic. Similarly, they can be created in a uniform way by the `Factory`, which is useful when you want to generate objects whose exact kind is unknown at compile time.

4.1.1 Parametric Curves

`ParamCurve` is the base class for all parametric curves in GoTools and defines a common interface. Many operations do not need to distinguish between different types of parametric curves. A parametric curve has (with some exceptions) the following functionality:

- operations on the curve
 - `clone`: make a copy of this curve
 - `subCurve`: create a subcurve of this curve
 - `appendCurve`: append another curve to this curve
 - `split`: split the curve into two curves at a given parameter
- operations in the parameter interval

- [startparam](#): fetch start parameter
- [endparam](#): fetch end parameter
- [setParameterInterval](#): linearly reparametrize the parameter interval
- [reverseParameterDirection](#): reverse the parameter interval
- evaluations
 - [point](#): evaluate the curve's position (and perhaps a certain number of derivatives) at a given parameter
 - [uniformEvaluator](#): evaluate the curve's position at a regular set of parameter values
- geometric information retrieval
 - [length](#): compute the length of (a segment of) the curve
 - [estimatedCurveLength](#): estimate the length of (a segment of) the curve
 - [compositeBox](#): compute a composite box (bounding box) enclosing the curve
 - [directionCone](#): compute a directional cone containing all tangent directions of this curve
- closest point computations
 - [closestPointGeneric](#): compute the closest point on (a segment of) this curve to a specified point — generic implementation
 - [closestPoint](#): compute the closest point on (a segment of) this curve to a specified point — specific implementation for each parametric curve type
- checks for degeneracy, symmetry, and type
 - [isLinear](#): check if the curve is linear
 - [isInPlane](#): check if the curve is contained in a plane belonging to a given pencil of planes
 - [isAxisRotational](#): check if the curve is axis rotational
 - [isDegenerate](#): check whether the curve degenerates to a single point
 - [isClosed](#): check whether the curve is closed

4.1.2 Parametric Surfaces

[ParamSurface](#) is the base class for a parametric surface and defines the common interface for all parametric surfaces. A parametric surface has (with some exceptions) the following functionality:

- operations on the surface
 - [clone](#): make a copy of this surface
 - [subSurfaces](#): create subsurfaces of this surface
 - [asSplineSurface](#): create a spline surface represented by this surface, if any
 - [outerBoundaryLoop](#): fetch the anticlockwise, outer boundary loop of the surface
 - [allBoundaryLoops](#): fetch the anticlockwise outer boundary loop of the surface, together with clockwise loops of any interior boundaries
 - [getBoundaryInfo](#): compute the boundary curve segment between two points on the boundary, as well as the cross-tangent curve
 - [mirrorSurface](#): reflect the surface through a given plane
 - [getInternalPoint](#): fetch an (unspecified) internal point in the surface
 - [constParamCurves](#): fetch the curve(s) obtained by intersecting the surface with one of its isoparametric curves
 - [nextSegmentVal](#): determine the parameter value of the start of the 'next segment' from a parameter value, along a given parameter direction

- [turnOrientation](#): flip the direction of the normal of the surface
- [getCornerPoints](#): fetch surface corners, geometric and parametric points
- operations in the parameter domain
 - [setParameterDomain](#): set the parameter domain to a given rectangle
 - [parameterDomain](#): fetch the parameter domain
 - [containingDomain](#): fetch a rectangular domain that contains the parameter domain
 - [inDomain](#): check if a parameter pair lies in the parameter domain
 - [inDomain2](#): check if a parameter pair lies inside, on the boundary, or outside of the parameter domain
 - [onBoundary](#): check if a parameter pair lies on the boundary of the parameter domain
 - [closestInDomain](#): fetch the parameter value in the parameter domain closest to a given parameter pair
 - [reverseParameterDirection](#): reverse one of the parameter directions
 - [swapParameterDirection](#): swap the two parameter directions
- geometric information retrieval
 - [normalCone](#): create a direction cone containing all surface normals
 - [tangentCone](#): create a direction cone containing all surface tangents in a given parameter direction
 - [compositeBox](#): compute a composite box (bounding box) enclosing the surface
 - [area](#): compute the total area of this surface
 - [estimateSfSize](#): estimate the size of the surface in the two parameter directions
- evaluations
 - [point](#): evaluate the surface's position (and perhaps a certain number of derivatives) at a given parameter pair
 - [normal](#): evaluate the surface normal for a given parameter pair
 - [evalGrid](#): evaluate the surface's position at a grid in the parameter domain
- closest point computations
 - [closestPoint](#): iteratively find the closest point on the surface to a given point
 - [closestBoundaryPoint](#): iteratively find the closest point on the boundary of the surface to a given point
 - [setIterator](#): set type of closest point iterator
- checks for degeneracy, symmetry, and type
 - [isDegenerate](#): check whether one of the four boundary curves is degenerate (i.e., has zero length)
 - [getDegenerateCorners](#): find degenerate surface corners by checking for parallel and anti-parallel partial derivatives
 - [isIsoTrimmed](#): check if the surface is trimmed along constant parameter curves
 - [isSpline](#): check if the surface is of type spline
 - [isAxisRotational](#): check if the surface is axis rotational
 - [isPlanar](#): check if the surface is planar
 - [isLinear](#): check if the surface is linear in one or both directions
 - [ElementOnBoundary](#): check if a polynomial element (for spline surfaces) intersects the (trimming) boundaries
 - [ElementBoundaryStatus](#): check if a polynomial element (for spline surfaces) intersects the (trimming) boundaries, is inside or outside

4.2 B-spline Curves

A B-spline curve is represented by the [SplineCurve](#) class.

Mathematically, the curve is defined by the parametrization

$$\mathbf{c}(t) = \sum_{i=1}^n \mathbf{p}_i B_{i,k,t}(t).$$

The dimension dim of the curve c is equal to that of its *control points* \mathbf{p}_i . For example, if the dimension of the control points is one, the curve is a function, if the dimension is two, the curve is planar, and if the dimension is three, the curve is spatial. Usually the dimension of the curve will be at most three, but higher dimensions are allowed.

A B-spline curve is a linear combination of a sequence of [B-splines](#) $B_{i,k,t}$ (called a B-basis) uniquely determined by a knot vector \mathbf{t} and the order k . The order is equal to the polynomial degree plus one. For example, if the order is two, the degree is one and the B-splines and the curve c they generate are (piecewise) linear. If the order is three, the degree is two and the B-splines and the curve are quadratic. Cubic B-splines and curves have order 4 and degree 3, etc.

The parameter range of a B-spline curve c is the interval $[t_k, t_{n+1}]$, and so mathematically, the curve is a mapping $c : [t_k, t_{n+1}] \rightarrow \mathbf{R}^{dim}$, where dim is the Euclidean space dimension of its control points.

The complete representation of a B-spline curve consists of

- dim : The dimension of the underlying Euclidean space, 1, 2, 3, ...
- n : The number of control points (also the number of B-splines)
- k : The order (polynomial degree + 1) of the B-splines.
- \mathbf{t} : The knot vector of the B-splines. $\mathbf{t} = (t_1, t_2, \dots, t_{n+k})$.
- \mathbf{p} : The control points of the B-spline curve. $p_{d,i}$, $d = 1, \dots, dim$, $i = 1, \dots, n$. E.g. when $dim = 3$, we have $\mathbf{p} = (x_1, y_1, z_1, x_2, y_2, z_2, \dots, x_n, y_n, z_n)$.

We note that arrays in c start at index 0 which means, for example, that if the array t holds the knot vector, then $t[0] = t_1, \dots, t[n+k-1] = t_{n+k}$ and the parameter interval goes from $t[k-1]$ to $t[n]$. Similar considerations apply to the other arrays.

The data in the curve representation must satisfy certain conditions:

- The knot vector must be non-decreasing: $t_i \leq t_{i+1}$. Moreover, the knots t_i and t_{i+k} must be distinct: $t_i < t_{i+k}$.
- The number of control points should be greater than or equal to the order of the curve: $n \geq k$.

To understand the representation better, we will look at three parts of the representation: the B-splines (the basis functions), the knot vector and the control polygon.

4.2.1 B-spline Basis Functions

The spline space is represented by the class [BsplineBasis](#). A set of B-spline basis functions is determined by the order k and the knots.

4.2.1.1 Linear B-splines

For example, to define a single basis function of degree one, we need three knots.

In the figure the three knots are marked as dots.

In the figure above the two knots at each end are equal.

By taking a linear combination of the three basis functions shown above, we can generate a linear spline function as shown in the next figure.

4.2.1.2 Quadratic B-splines

A quadratic B-spline basis function is a linear combination of two linear basis functions, in which the coefficients are linear affine in the parameter t . In the next figure, we will see a quadratic B-spline defined by four knots. A quadratic B-spline is the sum of two products, the first product between the linear B-spline on the left and a corresponding line from 0 to 1, the second product between the linear B-spline on the right and a corresponding line from 1 to 0.

4.2.1.3 Higher-order B-splines

For higher-order B-splines there is a similar definition. A B-spline of order $k \geq 2$ is a weighted linear combination of two B-splines of order $k - 1$. Explicitly, we define B-splines of order $k = 1$ as box functions,

$$B_{i,1}(t) = 1 \quad \text{if } t_i \leq t < t_{i+1} \quad \text{and } 0 \quad \text{otherwise}$$

and then the B-splines of order $k \geq 2$ as

$$B_{i,k}(t) = \frac{t - t_i}{t_{i+k-1} - t_i} B_{i,k-1}(t) + \frac{t_{i+k} - t}{t_{i+k} - t_{i+1}} B_{i-1,k-1}(t).$$

4.2.1.4 Basic properties

B-spline basis functions satisfy some important properties for curve and surface design. Each basis function is non-negative and it can be shown that they sum to one,

$$\sum_{i=1}^n B_{i,k,t}(t) = 1.$$

These properties combined mean that B-spline curves satisfy the *convex hull property*: the curve lies in the convex hull of its control points. Furthermore, the support of the B-spline basis function $B_{i,k,t}$ is the interval $[t_i, t_{i+k}]$ which means that B-spline curves has *local control*: moving one control point only alters the curve locally.

With k multiple knots at the ends of the knot vector, B-spline curves also have the *endpoint property*: the start point of the B-spline curve equals the first control point and the end point equals the last control point, in other words

$$\mathbf{c}(t_k) = \mathbf{p}_1 \quad \text{and} \quad \mathbf{c}(t_{n+1}) = \mathbf{p}_n.$$

4.2.2 The Control Polygon

The *control polygon* of a B-spline curve is the polygonal arc formed by its control points, $\mathbf{p}_0, \mathbf{p}_1, \dots, \mathbf{p}_n$. This means that the control polygon, regarded as a parametric curve, is itself a piecewise linear B-spline curve (order two), identical to its own control polygon. If we increase the order, the distance between the control polygon and the curve increases. A higher order B-spline curve tends to smooth the control polygon and at the same time mimic its shape. For example, if the control polygon is convex, so is the B-spline curve. Another property of the control polygon is that it will get closer to the curve if it is redefined by inserting knots into the curve and thereby increasing the number of control points. This can be seen in the next figure. In the limit, the refinement of the control polygon converges to its B-spline curve.

4.2.3 The Knot Vector

The knots of a B-spline curve describe the following properties of the curve:

- The parameterization of the B-spline curve
- The continuity at the joins between the adjacent polynomial segments of the B-spline curve.

Although the curves in the figure below have the same control polygon, they have different knot vectors and therefore different parametrizations.

This example is not meant as an encouragement to use parameterization for modelling, rather to make users aware of the effect of parameterization. Something close to curve length parameterization is in most cases preferable. For interpolation, chord-length parameterization is used in most cases.

The number of equal knots determines the degree of continuity. If k consecutive internal knots are equal, the curve is discontinuous. Similarly if $k - 1$ consecutive internal knots are equal, the curve is continuous but not in general differentiable. A continuously differentiable curve with a discontinuity in the second derivative can be modelled using $k - 2$ equal knots etc. Normally, B-spline curves in GoTools are expected to be continuous. For many algorithms, curves should be continuously differentiable (C^1).

4.2.4 NURBS Curves

A NURBS (Non-Uniform Rational B-Spline) curve is a generalization of a B-spline curve,

$$\mathbf{c}(t) = \frac{\sum_{i=1}^n w_i \mathbf{p}_i B_{i,k,\mathbf{t}}(t)}{\sum_{i=1}^n w_i B_{i,k,\mathbf{t}}(t)}.$$

In addition to the data of a B-spline curve, the NURBS curve \mathbf{c} has a sequence of weights w_1, \dots, w_n . One of the advantages of NURBS curves over B-spline curves is that they can be used to represent conic sections exactly (taking the order k to be three). A disadvantage is that NURBS curves depend nonlinearly on their weights, making some calculations, like the evaluation of derivatives, more complicated and less efficient than with B-spline curves.

The representation of a NURBS curve is the same as for a B-spline curve except that it also includes

- \mathbf{w} : A sequence of weights $\mathbf{w} = (w_1, w_2, \dots, w_n)$.

We make the assumption that the weights are strictly positive: $w_i > 0$.

Under this condition, a NURBS curve, like its B-spline cousin, enjoys the convex hull property. With k -fold knots at the ends of the knot vector, also NURBS curves have the endpoint interpolation property.

A NURBS curve is in GoTools stored using the same entities as non-rational spline curves. Note that the constructors of these entities assume that the NURBS coefficients are given in the format: $w_i \mathbf{p}_{i,1}, \dots, w_i \mathbf{p}_{i,dim}, w_i$ for $i = 1, \dots, n$, i.e., the coefficients are multiplied with the weights.

4.2.5 Spline Curve Functionality

In GoTools, [SplineCurve](#) inherits [ParamCurve](#) and has thereby the functionality specified for ParamCurve objects. Functionality specific for a B-spline curve can be found in the doxygen information. This functionality includes:

- Compute the derivative curve corresponding to a given curve
- Fetch information related to the spline space
- Fetch the control polygon of a spline curve
- Insert new knots into the knot vector of the curve and update the curve accordingly
- Increase the polynomial degree of the curve
- Make sure that the curve has got an open knot vector, i.e., knot multiplicity equal to the order in the ends of the curve

4.3 B-spline Surfaces

A tensor product B-spline surface is represented by the class [SplineSurface](#).

Mathematically, the B-spline surface is defined by the parametrization

$$\mathbf{s}(u, v) = \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \mathbf{p}_{i,j} B_{i,k_1,\mathbf{u}}(u) B_{j,k_2,\mathbf{v}}(v)$$

with control points $\mathbf{p}_{i,j}$ and two variables (or parameters) u and v . The formula shows that a basis function of a B-spline surface is a product of two basis functions of B-spline curves (B-splines). This is why a B-spline surface is called a tensor-product surface. The following is a list of the components of the representation:

- dim : The dimension of the underlying Euclidean space.
- n_1 : The number of control points with respect to the first parameter.
- n_2 : The number of control points with respect to the second parameter.
- k_1 : The order (polynomial degree + 1) of the B-splines in the first parameter.
- k_2 : The order of the B-splines in the second parameter.
- \mathbf{u} : The knot vector of the B-splines with respect to the first parameter, $\mathbf{u} = (u_1, u_2, \dots, u_{n_1+k_1})$.
- \mathbf{v} : The knot vector of the B-splines with respect to the second parameter, $\mathbf{v} = (v_1, v_2, \dots, v_{n_2+k_2})$.
- \mathbf{p} : The control points of the B-spline surface, $c_{d,i,j}$, $d = 1, \dots, dim$, $i = 1, \dots, n_1$, $j = 1, \dots, n_2$. When $dim = 3$, we have $\mathbf{p} = (x_{1,1}, y_{1,1}, z_{1,1}, x_{2,1}, y_{2,1}, z_{2,1}, \dots, x_{n_1,1}, y_{n_1,1}, z_{n_1,1}, \dots, x_{n_1,n_2}, y_{n_1,n_2}, z_{n_1,n_2})$.

The data of the B-spline surface must fulfill the following requirements:

- Both knot vectors must be non-decreasing.
- The number of control points must be greater than or equal to the order with respect to both parameters:
 $n_1 \geq k_1$ and $n_2 \geq k_2$.

The properties of the representation of a B-spline surface are similar to the properties of the representation of a B-spline curve. The control points $\mathbf{p}_{i,j}$ form a *control net* as shown in the figure below. The control net has similar properties to the control polygon of a B-spline curve, described above.

4.3.1 The Basis Functions

A basis function of a B-spline surface is the product of two basis functions corresponding to B-spline curves,

$$B_{i,k_1,\mathbf{u}}(u)B_{j,k_2,\mathbf{v}}(v).$$

Its support is the rectangle $[u_i, u_{i+k_1}] \times [v_j, v_{j+k_2}]$. If the basis functions in both directions are of degree one and all knots have multiplicity one, then the surface basis functions are pyramid-shaped. For higher degrees, the surface basis functions are bell shaped.

4.3.2 NURBS Surfaces

A NURBS (Non-Uniform Rational B-Spline) surface is a generalization of a B-spline surface,

$$s(u, v) = \frac{\sum_{i=1}^{n_1} \sum_{j=1}^{n_2} w_{i,j} \mathbf{P}_{i,j} B_{i,k_1,\mathbf{u}}(u) B_{j,k_2,\mathbf{v}}(v)}{\sum_{i=1}^{n_1} \sum_{j=1}^{n_2} w_{i,j} B_{i,k_1,\mathbf{u}}(u) B_{j,k_2,\mathbf{v}}(v)}.$$

In addition to the data of a B-spline surface, the NURBS surface has a weights $w_{i,j}$. NURBS surfaces can be used to exactly represent several common 'analytic' surfaces such as spheres, cylinders, tori, and cones. A disadvantage is that NURBS surfaces depend nonlinearly on their weights, making some calculations less efficient.

The representation of a NURBS surface is the same as for a B-spline surface except that it also includes

- \mathbf{w} : The weights of the NURBS surface, $w_{i,j}$, $i = 1, \dots, n_1$, $j = 1, \dots, n_2$, so $\mathbf{w} = (w_{1,1}, w_{2,1}, \dots, w_{n_1,1}, \dots, w_{1,2}, \dots, w_{n_1,n_2})$.

The weights are required to be strictly positive: $w_{i,j} > 0$.

The NURBS surface is represented by [SISLSurf](#) and [SplineSurface](#) in SISL and GoTools, respectively. As for the curve case, the constructors of [SISLSurf](#) and [SplineSurface](#) expect the coefficients to be multiplied with the weights.

4.3.3 Spline Surface Functionality

[SplineSurface](#) inherits [ParamSurface](#) in the GoTools data structure and implements the functionality described for [ParamSurface](#). Important additional functionality is listed below:

- Compute the derivative surface and normal surface corresponding to a given surface
- Fetch information related to the spline spaces
- Fetch the control polygon of a spline surface
- Fetch all weights of a NURBS surface
- Grid evaluation of the basis functions related to a surface
- Grid evaluation of the surface
- Insert new knots into the knot vectors of the surface and adapt the surface description accordingly
- Increase the polynomial degrees of the surface
- Fetch information related to the boundary curves of a surface

4.4 Other Curve Types

As shown in the class hierarchy, a spline curve is not the only parametric curve in GoTools although it is the most important one. There are also other curves that share parts of the public interface:

- **BoundedCurve** A bounded curve is a restriction of a parametric curve to a given interval. The interval can be specified either in parameter space, in geometry space or both. In the last case, it must be specified whether the parameter space bound or the geometry space bound is the master.
- **ElementaryCurve** An elementary curve is a container for a conic section or a line. This entity will be described in some detail later.
- **CurveOnSurface** This class represents a curve lying on a surface.

4.4.1 Curve On Surface

The **CurveOnSurface** entity is often related to a bounded, or trimmed, surface. A bounded surface is limited by a curve loop where each curve in the loop most often is represented by a **CurveOnSurface**. However, a **CurveOnSurface** is an entity in its own right. It simply represents a curve lying on a surface. It can for instance originate from intersecting the surface with a plane.

A **CurveOnSurface** consists of a parametric surface and two corresponding curves, one curve in the parameter domain of the surface and one spatial curve. The master representation is specified. Some operations may require the existence of one particular of these curves, in particular the parameter curve is requested. It exists functions that compute the missing curve from the existing one.

4.4.2 Elementary Curve

An **elementary curve** is a fairly new concept in GoTools, and until now such curves have been entered as entities in an IGES or STEP file. The elementary curves may also be represented as spline curves although non-bounded curves must be given a finite extension. The elementary curves is of the types:

- **Circle** The circle is defined by its center and radius and the plane in which it lies if the dimension of the geometry space is larger than 2. A circle is parameterized in terms of the angle. This is a bounded parameterization.
- **Ellipse** An ellipse is represented by a centre, the direction of one semi-axis and the length of the two semi-axis. The plane in which the ellipse lies is required if the dimension of the geometry space is larger than 2. An ellipse is parameterized in terms of the angle which gives a bounded parameterization.
- **Line** A line is given by a point and a direction. It has an unbounded parameterization, $t \in [-\infty, \infty]$.
- **Parabola** A parabola is given by a position, C , a focal distance, F , and a coordinate system, $(\mathbf{x}, \mathbf{y}, \mathbf{z})$. It is described as $f(t) = C + F(t^2\mathbf{x} + 2t\mathbf{y})$ and has an unbounded parameterization, $t \in [-\infty, \infty]$.
- **Hyperbola** A hyperbola is given by a position, a coordinate system and two distances. The parameterization is unbounded.

4.5 Other Surface Types

Similar to the curve case, GoTools supports also other types of parametric surfaces than spline surfaces. The additional surface types are bounded surface, elementary surface and composite surface. The elementary surfaces are conic surfaces, plane and torus. A composite surface consists of a number of spline surfaces where the associated parameter domains are mapped into one composite domain. The class is not complete in the sense that it does not support all functions specified in the interface for a parametric surface.

4.5.1 Bounded Surface

A [bounded surface](#) is a trimmed surface defined by an underlying surface and a trimming loop. The underlying surface is a parametric surface and the loop consists of a closed sequence of ordered parametric curves, often of type `CurveOnSurface`. The trimming loop must lie on the surface and be continuous with respect to a given tolerance.

4.5.2 Elementary Surface

Also [elementary surfaces](#) are quite new in GoTools, and have been entered as entities from IGES or STEP. The elementary surfaces may also be represented as spline surfaces although non-bounded surfaces must be given a finite extension. Operations involving this curve may, however, be made more efficiently by the knowledge of the surface type. The elementary surfaces is of the types:

- [Cone](#) A cone is described by a location, the cone axis, the radius of the cross section corresponding to the location and the cone angle. The parameterization is given by the angle and the distance along the axis, thus it is unbounded in one parameter direction.
- [Cylinder](#) A cylinder is given by its centre and radius and the cylinder axis. It is parameterized by the angle around the circle and the distance in the axis direction.
- [Plane](#) A plane is given by a point and a normal. It has an unbounded parameterization in both parameter directions.
- [Sphere](#) A sphere is given by its centre and radius. It has an angular parameterization in both parameter directions and thereby bounded.
- [Torus](#) A torus is given by the minor and major radius, a location and an axis. The parameterization is angular in both parameter directions.
- [Disc](#) A disc is a part of a plane limited by a circle and given by its centre, radius, plane normal and an additional vector to generate a coordinate system.

The elementary surfaces described above is placed in a coordinate system to facilitate the parameterization. In addition to the geometric information given for each entity, remaining coordinate system information must be specified.

4.6 Geometry Construction

The combination of SISL and GoTools provide a lot of methods for geometry construction. They partly overlap. The GoTools functionality is outlined here. More details can be found in the appropriate classes and namespaces. The SISL geometry construction methods are described in the SISL manual.

The classes for parametric curves, surfaces and volumes in GoTools do not contain construction facilities. They are solely for operating on these entities. The construction is performed in separate classes.

4.6.1 Curve Construction

Construction of elementary curves are being done by their definition or they are read from an IGES file. The curve construction methods in GoTools are concerned with spline curves. The methods are split between two sub modules in gotools-core, namely geometry and creators. The relevant classes are

- [HermitInterpolator](#) The class is placed in geometry. Interpolates a set of points where each point is associated a tangent vector. The points must be parameterized. This is a local curve construction method.
- [SplineInterpolator](#) A set of methods to interpolate a set of points. Some methods accept tangent vectors associated to some points. The points must be parameterized. The class gives the possibility to set particular conditions in the endpoints of the curve. This is a global method for curve construction.
- [SplineApproximator](#) Approximation in the least squares sense. Parameterized points and a spline space must be given. This class and the two proceeding ones inherit the same class, link [Go::Interpolator](#) Interpolator, and share parts of the interface.
- [ApproxCurve](#) Make a curve approximating a set of points with a given accuracy. The points must be parameterized and it is possible to give an initial spline space. The method iteratively applies the method in the class [SmoothCurve](#). This class and the following ones lie in the sub module creators.
- [SmoothCurve](#) Approximate a set of parameterized data points with a spline curve using a least squares approximation with a smoothing term. The spline space must be given. The method can also be used to perform smoothing on a given curve.
- [AdaptCurve](#) Approximates an evaluator based curve with a given accuracy. The method is based on least squares approximation with a smoothing term and spline space refinement.
- [ApproxCrvToSeqs](#) Approximate a set of curve sequences by a set of B-spline curves within a given accuracy. The curves are represented in the same spline space.
- [HermiteAppC](#) Approximate an evaluator based curve represented by a sub class of the class [EvalCurve](#), by a spline curve. An hermite method is used, thus a C^1 continuous curve will be generated. The existing evaluator based curves are
 1. [A curve in the parameter domain](#) of a surface is represented as the projection of a 3D curve into the parameter domain of a given surface. The output curve lies in the parameter domain of the surface.
 2. Given data describing a [surface-surface intersection curve](#), the curve lying given offset distances from the two surface involved in the intersection and parameterized similar to the intersection curve is represented. This construction can be used to create a rolling ball blend.
 3. Given two approximations of the same intersection curves, reapproximate the [intersection curve](#).
 4. Given a [curve in the parameter domain](#) of a surface, the geometry space curve is evaluated.
 5. Represent [an offset curve](#) from a given space curve. The direction of the offset is given as an expression of corresponding curves.
 6. An [offset curve](#) to a given curve in the direction of a cross tangent curve constructed as a blend between tangent curves.
 7. A [parameter curve](#) of any type that is to be approximated by a spline curve.
- [HermiteAppS](#) Approximate an evaluator based curve set represented by a sub class of the class [EvalCurveSet](#). A number of curves defined in the same spline space are generated. One concrete evaluator based curve set exists currently:
 1. Given a surface, a curve in geometry space and a corresponding cross tangent curve, [the parameter curve](#) representing the projection of the geometry curve into the surface and the corresponding projection of the cross tangent in the parameter domain is represented.
 2. Given an [intersection curve](#) represented as two [CurveOnSurface](#) instances, reapproximate this intersection curve along with the two parameter domain curves representing this curve.
 3. Improve the accuracy of an existing [trimming curve](#).
 4. Given an intersection curve between two surfaces, offset these surfaces given distances and create the [intersections curve](#) between the offset surfaces and corresponding cross tangent curves that will give a smooth transition between the offset surfaces.

4.6.2 Surface Construction

Similar to the curve construction methods, these methods are placed in the sub modules geometry and creators.

- [SweepSurfaceCreator](#) The class lies in geometry. The class contains two methods; sweep a curve along another curve to create a surface and rotational sweep.
- [ApproxSurf](#) This class and the following lie in creators. A set of parameterized scattered data are approximated by a spline surface. The boundary curves to the surface can be defined a priori. The spline space must be given. The method iteratively applies the method in [SmoothSurface](#) and performs parameter iteration. It may also refine the spline space.
- [SmoothSurf](#) Approximate a set of parameterized scattered data points using a least squares approach with a smoothing term. The spline space must be given. The method can also be used to smooth a given surface.
- [LoftSurfaceCreator](#) constructs a surface by interpolating a number of non-rational spline curves.
- [CoonsPatchGen](#) Construct a surface interpolating 4 boundary curves. The curves may be attached cross tangent curves. To achieve interpolation, the boundary conditions must be consistent.
- [HahnsSurfaceGen](#) Fill an n -sided hole with n surfaces. $n = 3, 5$ or 6 .

4.7 The utils module

The 'utility' module was developed in parallel with the 'geometry' module, and contains various useful classes and functions related to math. / computational geometry, while not being directly related to splines.

4.7.1 Data structures

You can find templated arrays and optimised vectors.

4.7.2 Geometrical objects

The module contain some objects that are much used in computational geometry, like

- [points](#)
- [bounding boxes](#) , axis-aligned or [rotated](#) , eventually [composite](#)
- [rational](#) numbers
- [barycentric](#) coordinate systems
- [direction cones](#)

4.7.3 Misc.

- Compile-time computation of [factorials](#)
- A general, nonlinear [function minimizer](#) in an arbitrary number of variables. This can be useful in a great number of different settings!

4.8 Tessellation

The geometry entities are tessellated in `gotools-core` in the sub module `tessellator`. Depending on the type of the geometry object, the result of the tessellation is stored in [GenericTriMesh](#), [LineStrip](#), [QuadMesh](#) or [RegularMesh](#) which all inherit the abstract class [GeneralMesh](#). The tessellators in this module relate to a given resolution in each parameter direction of the geometry object.

A curve is tessellated by the class [CurveTessellator](#) and the tessellated curve is returned by the function `CurveTessellator::getMesh()` as a shared pointer to a `LineStrip` object. A rectangular surface is tessellated in [RectGridTessellator](#) and the tessellator returns a shared pointer to a `RegularMesh`. The triangles produced during tessellation is organized in a set of triangle strips. This structure is taken advantage of to improve the drawing efficiency. A trimmed surface is tessellated by [ParametricSurfaceTessellator](#) and the tessellation is represented as an unorganized bunch of triangles. The output from the functionality in the tessellation module is taken as input to the `GoTools` viewers and the actual drawing is performed using `openGL`.

Chapter 5

The g2-format, GoTools file format for geometry entities

The following geometry entities have read and write functionality using the g2-format:

- *SplineCurve*, entity code = 100,
- *CurveOnSurface*, entity code = 110,
- *Line*, entity code = 120,
- *Circle*, entity code = 130,
- *Ellipse*, entity code = 140,
- *BoundedCurve*, entity code = 150,
- *Hyperbola*, entity code = 160,
- *Parabola*, entity code = 170,
- *SplineSurface*, entity code = 200,
- *BoundedSurface*, entity code = 210,
- *SurfaceOnVolume*, entity code = 211,
- *GoBaryPolSurface*, entity code = 220,
- *GoHBSplineParamSurface*, entity code = 230,
- *CompositeSurface*, entity code = 240,
- *Plane*, entity code = 250,
- *Cylinder*, entity code = 260,
- *Sphere*, entity code = 270,
- *Cone*, entity code = 280,
- *Torus*, entity code = 290,
- *SurfaceOfRevolution*, entity code = 291,
- *Disc*, entity code = 292,
- *LRsplineSurface*, entity code = 293,

- *TSplineSurface*, entity code = 294,
- *Go3dsObject*, entity code = 300,
- *GoHeTriang*, entity code = 310,
- *GoSdTriang*, entity code = 320,
- *GoQuadMesh*, entity code = 330,
- *GoHybridMesh*, entity code = 340,
- *ParamTriang*, entity code = 350,
- *GoVrmlGeometry*, entity code = 360,
- *PointCloud*, entity code = 400,
- *LineCloud*, entity code = 410,
- *GoTriangleSets*, entity code = 500,
- *RectGrid*, entity code = 510,
- *SplineVolume*, entity code = 700,
- *Parallelepiped*, entity code = 720,
- *SphereVolume*, entity code = 721,
- *CylinderVolume*, entity code = 722,
- *ConeVolume*, entity code = 723,
- *TorusVolume*, entity code = 724

In the following the file format corresponding to most of the entities listed above will be described. Note that the g2-file format is a simple format that does not support pointers. Thus, duplication of information may occur.

5.1 The object header

All geometry entities are preceded by the object [ObjectHeader](#) in a stream. `ObjectHeader` contains information about the class type of the geometry object to follow and the version number of the file format. The format of the header is as follows:

- `class type` . The entity code given in the list above.
- `major version` . Always 1.
- `minor version` . Always 0.
- `auxillary data` . 0 if the default colour is chosen, 4 if the rgb-colour code is chosen. In the latter case, the entity is followed by 4 integer digits between 0 and 255 giving the colours red, green and blue and the xxx.

5.2 SplineCurve

The entity code 100 is given in the header. [SplineCurve](#) continues with the following information

- dimension of geometry space, whether or not the curve is rational: 1=rational, 0=non-rational
- the number of coefficients, the polynomial order (i.e. degree+1)
- the knot vector, multiple knots are represented by giving the knot value several times
- the curve coefficients

The curve coefficients are given continuously, normally divided by a carriage return for each coefficient. The sequence is, in the non-rational case, (x_i, y_i, z_i) , $i = 1, \dots, n$ where n is the number of coefficients. In the rational case, the coefficients are given as $(x_i h_i, y_i h_i, z_i h_i, h_i)$, $i = 1, \dots, n$. h_i is the weight associated the current coefficient. Note that the coefficients are represented with the weight multiplied with the x , y and z -value.

A linear non-rational spline curve with no inner knots in the parameter interval $[0,1]$ is including the header given as:

```
100 1 0 0
3 0
2 2
0 0 1 1
0 0 0
1 0 0
```

5.3 CurveOnSurface

The entity enumeration of a [CurveOnSurface](#) is 110. The remaining file format is as follows:

- whether or not the parameter space curve is the master information (1=parameter curve is master, 0=space curve is master), the entity type of the parameter curve (0 if no such curve exists), the entity type of the space curve (0 if no such curve exists)
- the description of the parameter curve according to the rules for that curve type
- the description of the space curve according to the rules for that curve type

Either the parameter curve, the space curve or both are given. Information regarding constant parameter information for the curve on surface is not covered by the file format.

Note that the CurveOnSurface entity does also contain information about a [ParamSurface](#). Thus, the g2-representation of a CurveOnSurface is not stand alone. It needs to be combined with a [BoundedSurface](#). That section gives an example of how the CurveOnSurface entity is used in this context.

5.4 Line

The [line](#) is given by the following information:

- the dimension of the geometry space
- a point on the line
- the direction of the line
- a flag, 0 or 1, for unbounded or bounded
- if the line is bounded, the start and end parameters

The entity enumeration for a line is 120.

5.5 Circle

The [circle](#) is given by:

- the dimension of the geometry space
- the radius of the circle
- the centre of the circle
- the normal of the plane in which the circle lies
- the vector from the centre of the circle towards the "x-axis" - the start point of the default parametrization of the circle
- the start and end parameters

The circle has a default implicit parametrization from 0 to 2π .

The entity enumeration for a circle is 130.

Example:

```
130 1 0 0
dim
rad
c_x c_y c_z
n_x n_y n_z
v_x v_y v_z
```

5.6 Ellipse

The [ellipse](#) is given by:

- the dimension of the geometry space
- the major radius of the ellipse
- the minor radius of the ellipse
- the centre of the ellipse
- the normal of the plane in which the ellipse lies
- the vector from the centre of the ellipse towards the "x-axis" - the start point of the default parametrization

The entity enumeration for an ellipse is 130.

5.7 Bounded Curve

A [bounded curve](#) are expected to be bounded both parametrically and geometrically. Thus, a parameter on whether or not the limitation in the parameter space or in geometry space is preferred is included in the format. The format is:

- Whether the limitation in the parameter space is the master (1 if true)
- The start parameter of the bounded curve, the end parameter of the bounded curve
- The start point of the bounded curve in geometry space
- The end point of the bounded curve in geometry space
- The underlying curve described according to its entity type

All the information listed above is expected to be given in a g2-file. The corresponding entity enumeration is 150.

A bounded line from the point (0,0,0) to (1,0,0) where the position in space is the master regarding the bounding points is expressed as

```
150 1 0 0
120 0
0 1
3
0 0 0
1 0 0

3
0 0 0
1 0 0
```

120 is the entity number for a line and the dimension of the geometry space is 3.

5.8 SplineSurface

The entity enumeration for a [spline surface](#) is 200. The body of a spline surface is as follows:

- dimension of geometry space, whether or not the surface is rational: 1=rational, 0=non-rational
- the number of coefficients in the first parameter direction, the polynomial order in this direction (i.e. degree+1)
- the knot vector in the first parameter direction, multiple knots are represented by giving the knot value several times
- the number of coefficients in the second parameter direction, the polynomial order in this direction (i.e. degree+1)
- the knot vector in the second parameter direction
- the surface coefficients

The surface coefficients are given continuously and the 1. parameter direction runs fastest. The sequence is $(x_{(1,1)}, y_{(1,1)}, z_{(1,1)}), (x_{(2,1)}, y_{(2,1)}, z_{(2,1)}), \dots, (x_{(n,1)}, y_{(n,1)}, z_{(n,1)}), (x_{(1,2)}, y_{(1,2)}, z_{(1,2)}), \dots, (x_{(n,2)}, y_{(n,2)}, z_{(n,2)}), \dots, (x_{(1,m)})$. Here n is the number of coefficients in the 1. parameter direction, and m is the number of coefficients in the 2. parameter direction. The weights are multiplied with the coefficients similarly to the case for the spline curve and is given as an extra entity for each coefficient, again similar to the curve case.

A simple non-rational, bilinear surface with no inner knots is represented as:

```

200 1 0 0
3 0
2 2
0 0 1 1
2 2
0 0 1 1
0 0 0
1 0 0
0 1 0
1 1 0

```

5.9 BoundedSurface

[BoundedSurface](#) has entity enumeration 210. A bounded surface consists of an underlying rectangular parametric surface and one or more trimming loops. The file format body consists of the following information:

- The underlying surface represented according to its type
- The number of trimming loops
- For each trimming loop
 1. The number of curves in the current trimming loop
 2. The tolerance within which the loop is found to be continuous
 3. The curves in the trimming loop, one by one

The trimming curves are of type [ParamCurve](#), but in most cases they will be represented as [CurveOnSurface](#).

The following example illustrates the format a bounded surface. The underlying surface is a plane as can be seen from the entity number in line two. The 3 curves in the trimming loop are all of type [CurveOnSurface](#). Note that the entity number of [CurveOnSurface](#) does not appear. The space curve corresponding to the curve on surface is the master, and the only curve describing the trimming curve. This is given by the line `0 0 100` which occur for every curve and is to be interpreted: *the space curve is the master, the parameter curve does not exist, the space curve is a spline curve*. Following this line is the body of a spline curve in the g2-format.

```

210 1 0 0
250
3
0 0 0
0 0 1
1 0 0
1
-3 3
-3 3
0

1
3 0.0001

0 0 100
3 0
2 2
0 0 1 1
-1 0 0
0 -1 0

0 0 100
3 0
2 2
0 0 1 1
0 -1 0
-0.5 2 0

0 0 100

```

```

3 0
4 3
0 0 0 0.5 1 1 1
-0.5 2 0
-1 2 0
-2 1 0
-1 0 0

```

In this case the two first trimming curves are linear spline curves while the last one is of order 3 (degree 2) and has one inner knot. All the curves are non-rational.

5.10 Plane

A [Plane](#) has entity enumeration 250 and the body related to the g2-formation contains:

- The dimension of the geometry space
- A point in the plane
- The normal of the plane
- One vector in the set of vectors spanning the plane
- A flag, 0 or 1, for unbounded or bounded
- If the plane is bounded, the four bounds: *umin*, *umax*, *vmin*, *vmax*
- A flag, 0 or 1, indicating whether or not the *u* and *v* parameter directions are swapped.

The plane used as an underlying surface in the previous example has the format:

```

250 1 0 0
3
0 0 0
0 0 1
1 0 0
1
-3 3
-3 3
0

```

5.11 Cylinder

A [Cylinder](#) has entity enumeration 260 and the body related to the g2-formation contains:

- The dimension of the geometry space
- The cylinder radius
- A point on the cylinder axis
- The cylinder axis
- The vector from the cylinder axis towards the cylinder surface giving the start point of the default parametrization
- A flag, 0 or 1, for unbounded or bounded in the linear direction
- If unbounded, the bounding parameters: *umin*, *umax*
- If bounded, the bounding parameters: *umin*, *umax*, *vmin*, *vmax*
- A flag, 0 or 1, indicating whether or not the *u* and *v* parameter directions are swapped

5.12 Sphere

A [Sphere](#) has entity enumeration 270 and the body related to the g2-formation contains:

- The dimension of the geometry space
- The radius of the sphere
- The centre of the sphere
- The axis on which the degeneracies of a NURBS representation of the sphere will lie, i.e. the sphere axis
- The vector from the sphere axis towards the sphere surface giving the start point of the default parametrization
- The bounding parameters: *umin*, *umax*, *vmin*, *vmax*
- A flag, 0 or 1, indicating whether or not the *u* and *v* parameter directions are swapped

A sphere with centre in (1.5, 0, 0) and radius 1.5 represented in the g2-format is

```
270 1 0 0
3
1.5
1.5 0 0
0 0 1
1 0 0
0 6.283185307179586
-1.5707963267948966 1.5707963267948966
0
```

5.13 Cone

A [Cone](#) has entity enumeration 280 and the body related to the g2-formation contains:

- The dimension of the geometry space
- The cone radius at the position of the point on the cone axis
- A point on the cone axis
- The cone axis
- The vector from the cone axis towards the cone surface giving the start point of the default parametrization
- The opening angle of the cone
- A flag, 0 or 1, for unbounded or bounded in the linear direction
- If unbounded, the bounding parameters: *umin*, *umax*
- If bounded, the bounding parameters: *umin*, *umax*, *vmin*, *vmax*
- A flag, 0 or 1, indicating whether or not the *u* and *v* parameter directions are swapped

5.14 Torus

A [Torus](#) has entity enumeration 290 and the body related to the g2-formation contains:

- The dimension of the geometry space
- The major radius of the torus
- The minor radius of the torus
- The torus centre
- The mid axis of the torus
- The vector from the torus centre to the torus surface giving the startpoint of the default parametrization
- Select outer (1=yes, 0=no): Defines the parameter domain of the torus in degenerate cases.
- A flag, 0 or 1, for unbounded or bounded in the linear direction
- If unbounded, the bounding parameters: $umin, umax$
- If bounded, the bounding parameters: $umin, umax, vmin, vmax$
- A flag, 0 or 1, indicating whether or not the u and v parameter directions are swapped

5.15 SurfaceOfRevolution

A [SurfaceOfRevolution](#) has entity enumeration 291 and the body contains:

- The dimension of the geometry space
- A point of the axis of revolution
- The direction of the axis of revolution
- The *body* of the *spline curve* to rotate around this axis

A surface of revolution is

```

291 1 0 0
3
0 0 0
0 0 1

3 0
2 2
0 0 1 1
1 0 0
3 0 0

```

5.16 Disc

The entity number for [Disc](#) is 292. The g2 body contains:

- The dimension of the geometry space
- The centre of the disc
- The disc radius
- The normal to the disc surface
- A vector from the disc centre to the disc boundary to give a start point for the parametrization
- Whether a NURBS representation should have a degeneracy in the centre (=1) or have degenerate corners (=0)
- The angles giving the four degeneracy points at the boundary. Not used if the flag for centre degeneracy is false.

5.17 PointCloud

A [PointCloud](#) has enumeration 400. It has the following body:

- Number of points
- The coordinates of each point. The points are given one by one.

The dimension of a point in a point cloud is 3 by default. An example of a point cloud with 3 points is

```
400 1 0 0
3
0 0 0
1 0 0
1 1 0
```

5.18 LineCloud

A [LineCloud](#) has enumeration 410. It has the following body:

- Number of line segments
- The coordinates of the endpoints of each line segments. The lines are given one by one.

The dimension of a line in a line cloud is 3 by default. A line cloud with 3 lines follow:

```
410 1 0 0
3
0 0 0 0 0 1
1 0 0 1 0 1
1 1 0 1 1 1
```

5.19 SplineVolume

The entity enumeration for a [spline volume](#) is 700. The spline volume entity is placed in the module trivariate. The body of a spline volume is as follows:

- dimension of geometry space, whether or not the volume is rational: 1=rational, 0=non-rational
- the number of coefficients in the first parameter direction, the polynomial order in this direction (i.e. degree+1)
- the knot vector in the first parameter direction, multiple knots are represented by giving the knot value several times
- the number of coefficients in the second parameter direction, the polynomial order in this direction (i.e. degree+1)
- the knot vector in the second parameter direction
- the number of coefficients in the third parameter direction, the polynomial order in this direction (i.e. degree+1)
- the knot vector in the third parameter direction
- the volume coefficients

The volume coefficients are given continuously and the 1. parameter direction runs fastest, the 2. parameter direction is next and the 3. parameter direction is the most slow. For a non-rational spline volume in the 3-dimensional space, the sequence is $(x_{(1,1,1)}, y_{(1,1,1)}, z_{(1,1,1)}), (x_{(2,1,1)}, y_{(2,1,1)}, z_{(2,1,1)}), \dots, (x_{(n,1,1)}, y_{(n,1,1)}, z_{(n,1,1)}), (x_{(1,2,1)}, y_{(1,2,1)}, z_{(1,2,1)})$. Here n is the number of coefficients in the 1. parameter direction, m is the number of coefficients in the 2. parameter direction and p is the number of coefficients in the 3. parameter direction. The weights are multiplied with the coefficients similarly to the case for the spline curve and the spline surface and is given as an extra entity for each coefficient, again similar to the curve and surface case.

A simple non-rational, trilinear volume with no inner knots is represented as:

```
700 1 0 0
3 0
2 2
0 0 1 1
2 2
0 0 1 1
2 2
0 0 1 1
0 0 0
1 0 0
0 1 0
1 1 1
0 0 1
1 0 1
0 1 1
1 1 1
```

5.20 Parallelepiped

[Parallelepiped](#) has enumeration 720 and the following g2-format:

- Dimension of geometry space
- Lower right corner
- Unit vector in geometry space representing the first parameter direction
- Length of parallelepiped in the first direction
- Unit vector in geometry space representing the second parameter direction
- Length of parallelepiped in the second direction
- Unit vector in geometry space representing the third parameter direction
- Length of parallelepiped in the third direction

5.21 SphereVolume

[SphereVolume](#) has enumeration 721 and the following g2-format:

- Dimension of geometry space
- Sphere radius
- Centre of sphere
- Axis of sphere, i.e. the vector along which the degeneracies of a NURBS representation of the sphere will lie
- Vector from the centre to the outer surface giving input to the sphere parametrization

5.22 CylinderVolume

[CylinderVolume](#) has enumeration 722 and the following g2-format:

- Dimension of geometry space
- Cylinder centre
- Cylinder axis
- Vector from the centre to the outer surface giving input to the parametrization of the cylinder
- Minimum cylinder radius. If this number is larger than 0, the cylinder will have a hole along the axis
- Maximum radius, the radius of the outer cylinder surface
- Minimum height, =1: the cylinder is infinite, =0: the cylinder is finite and the distance from the centre to the bottom of the cylinder follows (positive or negative number)
- Maximum height, =1: the cylinder is infinite, =0: the cylinder is finite and the total height of the cylinder follows
- Whether a NURBS representation should have a degeneracy in the centre (=1) or have degenerate corners (=0)
- The angles giving the four degeneracy points at the boundary. Not used if the flag for centre degeneracy is false.

5.23 ConeVolume

[ConeVolume](#) has enumeration 723 and the following g2-format:

- Dimension of geometry space
- Radius of the cone at the centre
- A point at the cone axis (the centre)
- Cone axis
- The vector from the cone axis towards the boundary surface of the cone giving the start point of the cone parametrization
- The opening angle of the cone
- Minimum height the distance from the centre to the smallest end disc of the cone (positive or negative number)
- Maximum height, =1: the cone is infinite, =0: the cone is finite and the cone height follows
- Whether a NURBS representation should have a degeneracy in the centre (=1) or have degenerate corners (=0)
- The angles giving the four degeneracy points at the boundary. Not used if the flag for centre degeneracy is false.

5.24 TorusVolume

[TorusVolume](#) has enumeration 724 and the following g2-format:

- Dimension of geometry space
- The torus centre
- The normal to the plane through the big circle of the torus
- A vector from the torus centre to the torus surface giving the parametrization
- The major radius
- The minor radius
- Angle of revolution for the small circle
- Angle of revolution for the large circle
- Whether a NURBS representation should have a degeneracy in the centre (=1) or have degenerate corners (=0)
- The angles giving the four degeneracy points at the boundary. Not used if the flag for centre degeneracy is false.

Chapter 6

GoTools Igeslib

The [IGES converter](#) read an IGES file and represents its entites in the internal data structure of GoTools. It can also write a model represented in GoTools to an IGES file or convert between an IGES file and the [internal file format](#) of GoTools.

GoTools represent only geometric entities. Thus, IGES entities like annotation, structure, property, associativity, view, drawing and figure will be neglected. Neither are constructive solid geometry or finite element modelling entites handled. If such entities exist in a file read by the IGES converter, warning messages will be issued.

The topological entities specified in IGES 5.3 is not handled by the current version of the IGES converter. Thus, the entities vertex, edge, edge list, loop, face and shell is not handled. However, the geometric entities corresponding to these topological entities will be read. Colour information is read.

The content of an IGES file is transferred to the application as a vector of [GeomObjects](#). By checking the type of each object and acting thereafter, the model can be stored and handled in the GoTools environment.

To write an IGES file, the file entities are added one by one to the IGES converter using the function `addGeom` which takes a `GeomObject` as parameter. The actual file is written by the command `writeIGES`.

Chapter 7

GoTools Implicitization

Contains tools for implicitizing spline curves and surfaces. Also contains various classes for Bernstein polynomials.

Historically, the underlying ideas for implicitization and approximate implicitization were developed by Tor Dokken at SINTEF, ICT, in his Ph.D. thesis: [Aspects of Intersection Algorithms and Approximation](#), University of Oslo, Norway, 1997.

The implementations in this library was done in connection with the EU projects [GAIA I and II](#).

This module depends on the newmat matrix library, which is freely available from www.robertnz.net.

Chapter 8

GoTools Intersections

Contains tools for finding intersections of spline curves and surfaces.

This module depends on the newmat matrix library, which is freely available from www.robertnz.net.

Chapter 9

GoTools IsogeometricModel

Contains tools related to isogeometric analysis.

Chapter 10

GoTools LRsplines2D

This module contains classes and tools for working with LR spline surfaces.

Chapter 11

GoTools Parametrization

11.1 Purpose

The purpose of the GoTools Parametrization Library is to compute a reasonable parametrization for a discrete geometrical object. This geometrical object can be a planar graph embedded in R^2 or R^3 (triangulation, rectangular grid, etc.) or a point cloud without any explicit connectivity, but with an identified border.

There are many contexts for which such a parametrization is useful, for example when mapping textures onto polygonal meshes or when triangulating a surface from a set of scattered 3D points. The algorithms contained in this software are based on the work of Dr. Michael Floater.

11.2 How it can be used

This library has three degrees of freedom for specifying the parametrization:

- choice of *data structure*
- choice of *boundary parametrization*
- choice of *parametrization of the interior*

11.2.1 Choice of data structure

As mentioned in the last section, the data to be parametrized can be of various kinds, from general polygonal meshes (3D points and connectivity) to point clouds (no connectivity information, but boundary nodes must be identified and ordered). The various possible data types are given as sub-classes of [PrOrganizedPoints](#). You should choose the one that corresponds to the data that you want to parametrize. Many of these classes have read/write functionality for a generic format; you might want to reimplement these to correspond with the format of the data you are using. The list of currently available data structures are:

- [PrUnorganized_OP](#)
- [PrFastUnorganized_OP](#)
- [PrTriangulation_OP](#)
- [PrRectangularGrid_OP](#)
- [PrPlanarGraph_OP](#)

You can of course write a totally *new* specialization of the [PrOrganizedPoints](#) class, as long as you implement all the required member functions.

11.2.2 Choice of boundary parametrization

The boundary of the surface must be parametrized before the surface interior. This is done by the class [PrParametrizeBdy](#). There are several ways of parametrizing the boundary. You can specify the method you want to use through the [PrParametrizeBdy::setParamKind\(\)](#) member function. There are currently three options:

- `PrCHORDLENGTHBDY` - parametrize by chordlength (generally preferred)
- `PrCENTRIPETAL` - parametrize using square root of boundary point distances
- `PrUNIFBDY` - parametrize by imposing a fixed distance between each boundary point

Another thing that must be specified when determining the parametrization of the boundary is the *shape* of the parametrical domain. It can be a circle (default), or a rectangle (corners must be specified).

11.2.3 Choice of interior parametrization

The parametrization of the interior can also be done in several ways, which are each implemented as a sub-class of [PrParametrizeInt](#). Currently available methods are: (click on the links for individual explanations)

- [PrPrmMeanValue](#) (generally preferred)
- [PrPrmEDDHLS](#)
- [PrPrmLeastSquare](#)
- [PrPrmShpPres](#)
- [PrPrmUniform](#)

11.2.4 Putting it all together

The general procedure for parametrizing a data set can be summarized as follows:

- Prepare the data structure
 - establish an object of the appropriate datastructure (sub-class of [PrOrganizedPoints](#)). This object should be owned by a shared pointer (as found in the `boost` library).
 - read your data into the structure, either by using one of the provided member functions like [PrTriangulation_OP::scanRawData\(\)](#), [PrTriangulation_OP::scan\(\)](#), or by adding your own I/O-routines.
- Parametrize the boundary
 - Establish a [PrParametrizeBdy](#) object.
 - Associate it with your data by using the [PrParametrizeBdy::attach\(\)](#) function.
 - Choose parametrization type by calling the [PrParametrizeBdy::setParamKind\(\)](#) function.
 - Execute the parametrization by calling [PrParametrizeBdy\(\)](#). When calling this function without arguments, the parametrical domain will be a circle. A rectangular parameter domain can also be used. This is specified by additional arguments to the function.

- Parametrize the interior
 - When the boundary has been successfully parametrized, the interior can be treated. First, you need to instantiate an object of the desired sub-class of `PrParametrizeInt`.
 - Associate your data to this object by using the `PrParametrizeInt::attach()` function.
 - Carry out the parametrization by calling the `PrParametrizeInt::parametrize()` function.
- Accessing the result
 - The parametrization can be accessed in several ways, through the `PrOrganizedPoints` interface of your data structure:
 - * Several print routines can be used to dump all nodes with/without coordinates and associated parameters (`PrOrganizedPoints::printUVNodes`, `PrOrganizedPoints::printUVXYZNodes`, etc.).
 - * The parameters of an individual node can be accessed by the `PrOrganizedPoints::getU()` and `PrOrganizedPoints::getV()` functions.
 - Most of the sub-classes of `PrOrganizedPoints` also have `print()` and `scan()` functions that can be used for reading and writing their data to a stream.
 - You can write your own customised data access and streaming functions.

11.3 Example program

The procedure mentioned above can be observed in a working program located in the `examples` folder. The source file name is `demo.C`. The program is run from the command line, where you can also specify the data. It can handle both point clouds and triangulations. A sample triangulation is provided in the `data/` folder.

For instance, try

```
$ ./demo -i data/gjoevik_triang
```

(There are also more options you can specify; to see the list of options, run the program without any arguments).

If the input data is a triangulation (the case above), the resulting, parametrized triangulation will be saved in the file `triangulation`. In any case, the parametrization for each node/point will be dumped to the file `uv_nodes`.

Good luck!

Chapter 12

GoTools QualityModule

This GoTools module consists of a set of tools to check the quality of CAD models.

12.1 Tolerances

The tests make use of the tolerances associated with a surface model, i.e.

gap CAD models are seen as continuous if they are continuous within this tolerance. If the distance between two points are less than this tolerance, they are viewed as identical. A reasonable tolerance is in the specter $[10^{-6}, 10^{-2}]$, but it depends on the expected quality of a model.

neighbour This tolerance is used in adjacency analysis and it represents the maximum distance between neighbouring surfaces or curves. If two curves or surfaces lie more distant than this tolerance, the entities are found not to be adjacent. The neighbour tolerance should be larger than the gap tolerance. If nothing specific is known, a factor of 10 makes sense, but if the gap tolerance is really small, a larger factor should be used. Surfaces that lie closer to each other than the neighbouring tolerance is found to be adjacent, but if the distance between the surfaces somewhere is larger than the gap tolerance, the surface set contains gaps. This is an error in the model.

bend If two surfaces meet along a common boundary and corresponding surface normals form an angle which is larger than this tolerance, it is assumed that there is an intended sharp edge between the surfaces. Similarly, if two curves in a composite curve meet with an angle larger than this tolerance, there is an intentional corner.

kink If two adjacent curves or surfaces meet with an angle less than this tolerance, they are seen as G^1 continuous. If the angle is larger than this tolerance, but less than the bend tolerance, the intended G^1 continuity is broken and it is an error in the model. The tolerance depends on the continuity requirements of the application. One suggestion is 10^{-2} . The bend tolerance must be larger than the kink tolerance, for instance by a factor of 10. Both angular tolerances are given in radians.

12.2 Tests

The available quality tests can be classified as follows:

Face continuity Checks for continuity between faces in a surface model. Positional and tangential discontinuities with respect to the gap and the kink tolerance, respective, are returned. Discontinuities larger than the neighbour tolerance or bend tolerance are assumed to be intentional, and thus no error is reported.

Edge continuity Checks for positional and tangential discontinuity between edges in the model. The same tolerances are used as for face continuity.

Accuracy of bounding entities Whether or not the distance between an edge and its associated face, a vertex and its associated edges and a vertex and its associated faces is less than the gap tolerance.

Acute angles Check for acute angles between adjacent faces or edges. The kink tolerance is applied.

Degeneracies Identify surfaces with boundary curves degenerating to a point and surfaces with degenerate corners. Identify vanishing surface normals and curve tangents, intersections between boundary loops belonging to a trimmed surface and self intersections of boundary loops. The gap tolerance is used in the intersection and self intersection tests while the neighbour and kink tolerance is used in degeneracy tests. The gap tolerance is used in tests for vanishing tangents and normals.

Small entities Identify small edges, small faces, sliver surfaces, and narrow regions in faces. The narrow region test relates to the neighbour tolerance while the other tests use specific tolerances.

Consistency of orientation Check for consistency in loops, i.e. the curves defining the loop are head to tail oriented, or in surface models. For closed face sets, all surface normals should point out of the model or into it, preferable out. Also open face sets should have consistent surface normal directions at face boundaries. However, the face orientation test is currently not up to date and the result can unfortunately not be trusted.

Identical entities Check for identity of vertices, and identical or embedded faces or edges. The neighbourhood tolerance is used.

Spline entity testing Check spline curves and surfaces for G^1 and C^1 discontinuities. The test is localized to knots of high multiplicity. The gap and the kink tolerances are used for these tests. Check also for spline entities with close, but not identical knots. Such entities can create problems for certain operations. A specific tolerance is used in this test.

Compute curvature information with respect to single entities The minimum curvature radius and curvature radii less than a given threshold can be obtained. The test is applied to all curve or surface entities in a model.

The tests described above are localized in the class [FaceSetQuality](#). See the documentation of this class for more information.

Chapter 13

The filter routines main page

13.1 Introduction

This is a collection of routines for handling various (3x3x3) 3d filters.

020114: This REALLY REALLY must be cleaned up... 021231: Not yet, but soon, it will only be a question of removing commented out stuff... Hopefully... 050120: Changed return types for boolean functions from int to bool. Hope this doesn't break anything.

Chapter 14

GoTools Topology

This module contains functionality to perform topology analysis on a collection of faces. The adjacency analysis itself is performed in [FaceAdjacency](#), and the operations uses template faces and edges. The interfaces are given in [tpFace](#) and [tpEdge](#), respectively.

The module depends on the GoTools core library

Chapter 15

GoTools Trivariate

This module trivariate represents NURBS volumes and contains construction methods and operations related to such volumes.

This module depends on:

- GoTools Core library
- SISL library

15.1 Data Structures

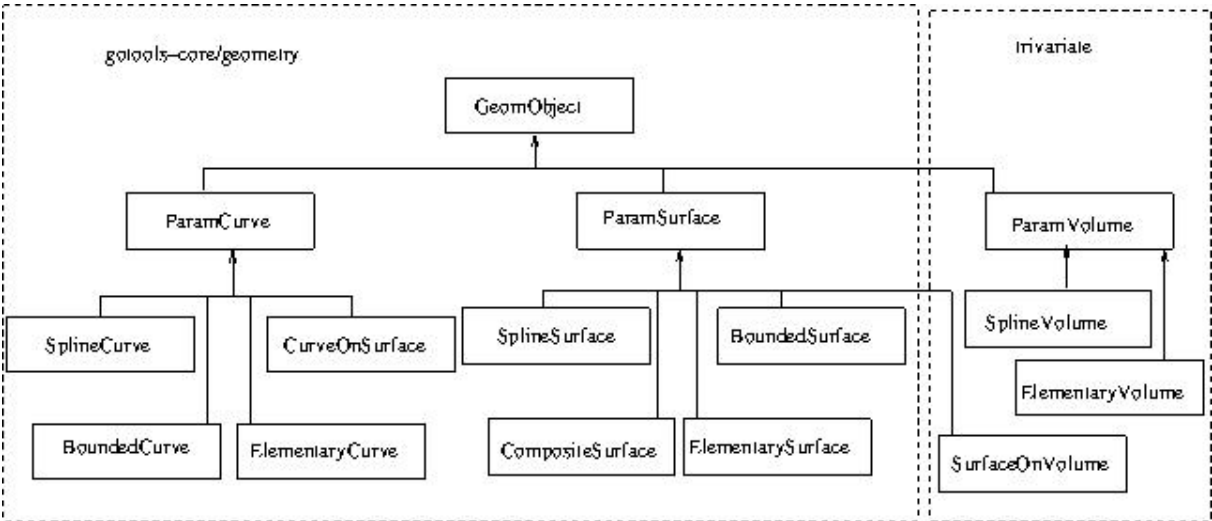

Figure 15.1 Simplified overview of the geometry class hierarchy

The figure above shows the main geometric classes in GoTools and how they are divided between modules.

15.2 B-spline Volumes

A B-spline volume is represented in [SplineVolume](#) in the GoTools module trivariate.

The volume is defined by the formula

$$\mathbf{V}(u, v, w) = \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \sum_{h=1}^{n_3} \mathbf{p}_{i,j,h} B_{i,k_1,\mathbf{u}}(u) B_{j,k_2,\mathbf{v}}(v) B_{h,k_3,\mathbf{w}}(w)$$

with control points $\mathbf{p}_{i,j,h}$ and three variables (or parameters) u , v and w . A basis function of a B-spline volume is a product of three basis functions of B-spline curves (B-splines).

The following is a list of the components of the representation:

- dim : The dimension of the underlying Euclidean space.
- n_1 : The number of control points with respect to the first parameter.
- n_2 : The number of control points with respect to the second parameter.
- n_3 : The number of control points with respect to the third parameter.
- k_1 : The order (polynomial degree + 1) of the B-splines in the first parameter.
- k_2 : The order of the B-splines in the second parameter.
- k_3 : The order of the B-splines in the third parameter.
- \mathbf{u} : The knot vector of the B-splines with respect to the first parameter, $\mathbf{u} = (u_1, u_2, \dots, u_{n_1+k_1})$.
- \mathbf{v} : The knot vector of the B-splines with respect to the second parameter, $\mathbf{v} = (v_1, v_2, \dots, v_{n_2+k_2})$.
- \mathbf{w} : The knot vector of the B-splines with respect to the third parameter, $\mathbf{w} = (w_1, w_2, \dots, w_{n_3+k_3})$.
- \mathbf{p} : The control points of the B-spline volume, $c_{d,i,j,h}$, $d = 1, \dots, dim$, $i = 1, \dots, n_1$, $j = 1, \dots, n_2$, $h = 1, \dots, n_3$. When $dim = 3$, we have $\mathbf{p} = (x_{1,1,1}, y_{1,1,1}, z_{1,1,1}, x_{2,1,1}, y_{2,1,1}, z_{2,1,1}, \dots, x_{n_1,1,1}, y_{n_1,1,1}, z_{n_1,1,1}, \dots, x_{n_1,n_2,1}, y_{n_1,n_2,1}, z_{n_1,n_2,1}, \dots, x_{n_1,n_2,n_3}, y_{n_1,n_2,n_3}, z_{n_1,n_2,n_3})$.

The data of the B-spline volume must fulfill the following requirements:

- All knot vectors must be non-decreasing.
- The number of control points must be greater than or equal to the order with respect to all three parameters: $n_1 \geq k_1$, $n_2 \geq k_2$ and $n_3 \geq k_3$.

The properties of the representation of a B-spline volume are similar to the properties of the representation of a B-spline curve or surface. The control points $\mathbf{p}_{i,j,h}$ form a *control net*. The control net has similar properties to the control polygon of a B-spline curve, described in the module `gotools-core`. A B-spline volume has three knot vectors, one for each parameter.

15.2.1 The Basis Functions

A [basis function](#) of a B-spline volume is the product of three basis functions corresponding to B-spline curves,

$$B_{i,k_1,\mathbf{u}}(u) B_{j,k_2,\mathbf{v}}(v) B_{h,k_3,\mathbf{w}}(w)$$

Its support is the box $[u_i, u_{i+k_1}] \times [v_j, v_{j+k_2}] \times [w_h, w_{h+k_3}]$.

15.2.2 NURBS Volumes

A NURBS (Non-Uniform Rational B-Spline) volume is a generalization of a B-spline volume,

$$\mathbf{V}(u, v, w) = \frac{\sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \sum_{r=1}^{n_3} h_{i,j,r} \mathbf{P}^{i,j,r} B_{i,k_1,u}(u) B_{j,k_2,v}(v) B_{r,k_3,w}(w)}{\sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \sum_{r=1}^{n_3} h_{i,j,r} B_{i,k_1,u}(u) B_{j,k_2,v}(v) B_{r,k_3,w}(w)}.$$

In addition to the data of a B-spline surface, the NURBS surface has a weights $h_{i,j,r}$. NURBS volumes can be used to exactly represent volumes that have common 'analytic' surfaces such as spheres, cylinders, tori, and cones as boundary surfaces. A disadvantage is that NURBS volume depend nonlinearly on their weights, making some calculations less efficient.

The representation of a NURBS volume is the same as for a B-spline volume except that it also includes

h: The weights of the NURBS volume, $h_{i,j,r}$, $i = 1, \dots, n_1$, $j = 1, \dots, n_2$, $r = 1, \dots, n_3$, so $\mathbf{h} = (h_{1,1,1}, h_{2,1,1}, \dots, h_{n_1,1,1}, h_{1,2,1}, \dots, h_{n_1,n_2,1}, \dots, h_{n_1,n_2,n_3})$.

The weights are required to be strictly positive: $h_{i,j,r} > 0$.

The NURBS volume is represented by `SplineVolume`. As for the curve and surface cases, the constructor expects the coefficients to be multiplied with the weights.

15.2.3 Spline Volume Functionality

The functionality of a [spline volume](#) to a large extend corresponds to the functionality of a spline surface. Important functionality is:

- A NURBS volume is able to make a copy of itself
- Compute the bounding box of the volume
- Evaluation and grid evaluation
- Grid evaluation of basis functions
- Compute the derivative volume corresponding to a volume
- Closest point computation
- Fetch a sub volume of a given volume
- Fetch information related to the spline spaces
- Swap and reverse parameter directions in a volume
- Fetch the control polygon of the volume
- Fetch all weights of a NURBS volume
- Insert knots into the spline spaces of the volume and adapt the volume description accordingly
- Increase the polynomial degree of the volume in one parameter direction
- Fetch a constant parameter surface from the volume
- Fetch all boundary surfaces surrounding a volume
- Check for periodicity and degeneracy

15.2.4 Construction Methods for SplineVolume

The following methods exist for construction of a spline volume. The corresponding GoTools class names are given in brackets.

- Sweep a NURBS surface along a NURBS curve ([SweepVolumeCreator](#)).
- Rotational sweep of a NURBS surface ([SweepVolumeCreator](#)).
- Lofting to interpolate a number of NURBS surfaces ([LoftVolumeCreator](#)).
- Interpolate 6 boundary surface to create a volume using a Coons patch approach ([CoonsPatchVolumeGen](#)). This functionality applies only to non-rational spline surfaces.
- Represent an [elementary volume](#) as a spline volume. An elementary volume is a [parametric volume](#) similarly to spline volumes. The elementary volumes are:
 1. [Sphere](#)
 2. [Cylinder](#)
 3. [Cone](#)
 4. [Parallelepiped](#)
 5. [Torus](#)

A spline volume may have a well behaved outer boundary, but a bad distribution of coefficients in the inner. This is in particular the case if the volume is constructed by a Coons patch approach. The positioning of the internal coefficients may be improved by smoothing. The coefficients at the boundaries are kept fixed and the coefficients in the inner are redistributed by solving a minimization problem. The smoothing is performed in the class [SmoothVolume](#).

15.3 Surface on Volume

The module trivariate provides a surface which extends the class of parametric surfaces defined in gotools-core, namely [SurfaceOnVolume](#). This surface inherits most of the functionality defined for parametric surfaces and takes the same role as [CurveOnSurface](#) for parametric curves. The surface possesses information about

- The associated volume
- The geometric description of this surface and/or
- The description of this surface in the parameter domain of the given volume
- Constant parameter and volume boundary information. If this surface for instance happens to be a constant parameter surface in the given volume, it knows the parameter direction and the associated constant parameter value.

15.4 Curves Related to a Parametric Volume

Two evaluator based curves can be used in together with [HermiteAppC](#) in gotools-core/creators exist, namely [VolumeParameterCurve](#) and [VolumeSpaceCurve](#).

Chapter 16

GoTools Trivariatemodel

The module trivariatemodel contains the representation format for a set of volumes and tools to act upon the volumemodel.

The module depends on:

- The GoTools Core library
- GoTools Composite Model
- GoTools Trivariate
- Modules that Composite Model depend upon

16.1 Volume Topology

The volume topology in GoTools is an extension to the boundary represented topology implemented in the module compositemodel. However, in contrast to the boundary represented topology, the volume topology is not manifold. Thus, we must expect more than two faces to meet in an edge.

The top entity in the topology structure is the volume model ([VolumeModel](#)) which consists of a set of volumes. Each volume has a topological entity implemented in [ftVolume](#) and a geometrical representation implemented as [ParamVolume](#). Information about the geometric representation of a volume can be found in the module trivariate.

[ftVolume](#) inherits [Body](#) in compositemodel and is, as [Body](#), surrounded by one or more shells represented as [SurfaceModels](#). A shell is a collection of faces ([ftSurface](#)) which have a geometric representation as a [Param↔Surface](#). [ParamSurface](#) is described in the module gotools-core.

A face is limited by a number of [loops](#) that are sequences of edges ([ftEdge](#)). In this context, the face is used to represent adjacency between volumes. An edge is limited by two [vertices](#).

16.2 Volume Model

`VolumeModel` is a [composite model](#) as illustrated in the figure above. See also the description in the documentation of composite model. As such it inherits a function interface, but some methods are not implemented. Thus, the class is incomplete, but not in the sense of being a topological entity.

`VolumeModel` has the following functionality:

- Fetch one entity in the set, either as a topological or geometric volume.
- Evaluate the volume model given information about which entity to evaluate
- Compute [bounding box](#)
- Add a new volume to the volume model
- Remove one volume from the volume model
- Check if all geometrical volumes are NURBS
- Fetch all [vertices](#) in the model
- Fetch all [radial edges](#) in the model
- Fetch non-radial edges, i.e. edges that does not belong to at least two volumes.
- Fetch all inner faces in the model
- Fetch all boundary faces in the model
- Check if the model has a corner-to-corner configuration
- Ensure that the model has a corner-to-corner configuration
- Ensure that adjacent spline volumes share common spline spaces at common boundaries
- Fetch the boundary of the volume model described as a number of `SurfaceModels`
- Divide the volume model into connected volume models

The constructor of the volume model requires a number of `comp_sec2`, namely `gap`, `neighbour`, `kink` and `bend`. These tolerances are the same as the ones required for a composite model, and the tolerances are explained in the documentation of the `compositemodel` module.

16.3 Topological Volume Entity

The topological volume entity is implemented in the class `ftVolume` and it inherits `Body` from the `compositemodel` module. The name `ftVolume` is chosen to be in line with `ftSurface` and `ftEdge`. Those entities have got their names for historical reasons. The prefix `ft` has no deeper meaning.

An `ftVolume` is a `Body` and has thus access to its shells, i.e. boundaries, and can check whether two `ftVolumes` are adjacent. An `ftVolume` can also

- Fetch the corresponding geometry volume
- Fetch the bounding box of this volume
- Fetch all adjacent `ftVolumes`
- Fetch all radial edges belonging to this volume or being common between this volume and another volume

- Fetch edges belonging only to the current volume
- Compute adjacency information between the current volume and another volume
- Return information about outer boundaries
- Get local information about correspondence of coefficients of two adjacent spline volumes
- Return the relation between the current volume and a given vertex

A `ftVolume` may be trimmed. That is, the boundary faces of the volume may limit the extent of the underlying parametric volume. In this context the following functionality apply:

- Check if the volume is hexahedral
- Approximate a hexahedral trimmed volume by one spline volume
- Split a trimmed volumes into a set of hexahedral trimmed volumes

Note that the functionality related to trimmed volumes are under development and currently very unstable and limited.

16.4 Extensions to Face

The initial implementation of a face as one entity in a boundary representation solid was no longer sufficient when the entity should serve as part of the boundary of a volume belonging to a volume model. Some extensions turned out to be required. The face `ftSurface` has knowledge about the `Body` it belongs to, if any. It has also a pointer to a boundary face belonging to an adjacent body. This pointer is used in the context of a volume model. During the assembly of a volume model, information about coincident boundary faces of the `ftVolumes` are computed, and the pointer representing adjacency is set accordingly.

An `ftSurface` provides access to its twin and to the, at most, two bodies sharing the common face represented by this `ftSurface`.

When the `ftSurface` represents the boundary surface of an `ftVolume`, the corresponding parametric surface will be of type `SurfaceOnVolume`. This class is implemented in the module `trivariate`. A `SurfaceOnVolume` has knowledge about the spatial representation of the surface, the `ParamVolume` on which it belongs and the position of the surface in the parameter domain of the volume. Currently, a `SurfaceOnVolume` is constructed only as a boundary surface of a `SplineVolume`. It contains enough information to identify which volume boundary it represents and the orientation of the surface compared to this boundary.

16.5 Radial Edge

In a non-manifold model, more than two faces can meet in an edge, and thus the half edge representation implemented in `ftEdge` is not sufficient to hold the model. The radial edge, `EdgeVertex`, is an extension to the topology structures of `compositemodel` and the class itself is placed in `compositemodel`. An `EdgeVertex` contains information of all pairs of half edges, `ftEdge`, meeting in an edge, and each `ftEdge` belonging to an `EdgeVertex` has access to this `EdgeVertex`.

An `EdgeVertex` instance is defined when adjacency between two `ftSurfaces` is found. Thus, at edges in an `ftVolume` where no adjacent `ftVolume` exists, no `EdgeVertex` instance will be defined. Then the edge is represented with a pair of `ftEdge` instances.

The `EdgeVertex` class is placed in the module `compositemodel`, but is used in connection with volume models. In addition to functionality related to topology build, the class has some access functionality:

- Fetch edges meeting in the radial edge, either uniquely defined, i.e. one instance for a pair or twins, or absolutely all edges.
- Fetch a specified edge
- Check if a ftEdge belongs to a radial edge
- Check if a ftEdge belongs to a radial edge and has no information about a corresponding ftEdge. In that case the corresponding surface does not belong to a volume.
- Fetch adjacent faces
- Fetch adjacent bodies

Chapter 17

Application Programming Interface to TTL (API)

There are two interface channels between TTL and the application data structure: `DartType` and `TraitsType`, which are template arguments to the TTL functions. Function templates in TTL use either `DartType` or both `DartType` and `TraitsType` depending on the complexity of the algorithms. `DartType` is used for topological queries, and `TraitsType` is used for topological modifiers and geometric calculations. The documentation in TTL tells which functionality is needed in `DartType` and `TraitsType` for each function template.

TTL consists of two namespaces with generic functions: `tll` contains the main interface and `tll_util` contains utility functions that can also be used by the application programmer. The figure below shows the (simple) architecture of an application using TTL.

In the following we explain how `DartType` and `TraitsType` must be implemented as an interface to the actual data structure. For more details see [literature](#).

17.1 DartType

The generic functions in TTL navigates in the application data structure through a "topological element" call a *dart*, which must be implemented as a struct or a class by the application programmer. A dart can be considered as a unique triple $d = (V, E, T)$, where V is a node of the edge E , and V and E is a node and an edge of the triangle T ; see figure a) below where a dart is indicated as an arrow.

TTL expects that three functions, which we call *alpha-iterators*, are present in the dart class: `alpha0()`, `alpha1()` and `alpha2()`. These functions reposition the dart in the triangulation as shown in figure b) above and return a reference to the modified dart itself. Thus, `alpha0()`, `alpha1()` and `alpha2()` change the node, the edge and the triangle of the triple $d = (V, E, T)$ respectively.

Note

- The *dart* is not part of the data structure. It is a "dynamic" element that "moves" around in the actual application data structure when the alpha-iterators are applied to it. Thus, this mechanism does not require any extra memory other than that occupied by the (few) darts that are involved in a function template of TTL that is called.

In addition to the alpha-iterators, TTL expects that standard class member functions such as constructors, assignment operators and the like are also implemented in the dart class.

The following syntax is required:

```

class MyDart {
    ...
public:
    // Constructors and destructors
    ...
    MyDart(const MyDart& dart) {...} // copy constructor
    MyDart& operator= (const MyDart& dart) {...} // assignment operator

    // comparing dart objects
    bool operator==(const MyDart& dart) const {...}
    bool operator!=(const MyDart& dart) const {...}

    // alpha-iterators
    MyDart& alpha0() {...; return *this;}
    MyDart& alpha1() {...; return *this;}
    MyDart& alpha2() {...; return *this;}
};

```

Thus, the alpha-iterators change the content of the dart and return a reference to the dart itself.

Note

- Note that `alpha2()` must return the dart itself without changing its content (when checked with the `==` operator) if the edge associated with the dart is at the boundary of the triangulation. The source code of [ttl::isBoundaryEdge](#) illustrates this:

```

template <class DartType>
bool isBoundaryEdge(const DartType& dart) {

    DartType dart_iter = dart;
    if (dart_iter.alpha2() == dart)
        return true;
    else
        return false;
}

```

Consult the definition and source code of class [hed::Dart](#), which implements the dart class for the half-edge data structure, for a thorough example.

17.2 TraitsType

`TraitsType` can be a static class or a struct that contains functionality required by the functions in TTL. The purpose with `TraitsType` is twofold:

- Let the application programmer provide topological modifiers on the actual data structure that are not resolved by TTL, e.g., remove a triangle from the triangulation,
- Let the application programmer provide basic geometric calculations and thus control the level of accuracy for such calculations.

For example, assume that a function in TTL requires a scalar product between vectors in the plane, represented as darts, with the following syntax:

```

real_type scalarProduct2d(const DartType& d1, const DartType& d2)

```

Then this function must be implemented in the traits class together with the definition of `real_type`:

```

struct MyTraitsType {
    typedef double real_type;
    ...
    static real_type scalarProduct2d(const MyDart& v1, const MyDart& v2) {
        return ::my_scalarProduct2d(v1,v2);
    }
    ...
    static bool swapTestDelaunay(const MyDart& dart) {
        if (dart.getEdge().isConstrained())
            return false;
        else
            return ttl::swapTestDelaunay<MyTraitsType>(dart);
    }
};

```

The second function, `swapTestDelaunay`, implements the Delaunay swapping test. The function decides if the edge associated with the given dart should be swapped according to the *circumcircle* criterion (or equivalently according to the *MaxMin* angle criterion). In the example above, it is first examined if the edge is constrained, in which case `false` is returned. Then the test is directed back to TTL again since the circumcircle test is present there; see [ttl::swapTestDelaunay](#). Of course, the user could also make his/her own implementation of the circumcircle test, e.g., by using robust schemes with exact arithmetic as Jonathan Richard Shewchuk does (<http://www-2.cs.cmu.edu/~quake/robust.html>).

This example also illustrates the syntax `functionName<MyTraitsType>(...arguments...)` when calling function templates using a traits class.

Actually, scalar product between vectors, as well as cross product and other point and vector algebra, are also present in the namespace `ttl_util`. Assume that `MyDart::x()` and `MyDart::y()` deliver the coordinates in the plane of the node associated with a dart. Then the scalar product in `MyTraitsType` can be implemented as:

```

static real_type scalarProduct2d(const MyDart& v1, const MyDart& v2) {
    MyDart v10 = v1; v10.alpha0();
    Dart v20 = v2; v20.alpha0();
    return ttl_util::scalarProduct2d(v10.x()-v1.x(), v10.y()-v1.y(),
                                    v20.x()-v2.x(), v20.y()-v2.y());
}

```

Consult the definition and source code of struct [hed::TTLtraits](#), which implements the traits class for the half-edge data structure. This example shows which members that are required in the traits class for running incremental Delaunay triangulation and removing nodes in a triangulation.

Chapter 18

Example using TTL and the half-edge data structure

Chapter 19

The Half-Edge Data Structure and Adaption to TTL

An implementation of the the well-known *half-edge* data structure for triangulations is documented briefly on these pages together with adaption of this data structure to [TTL, The Triangulation Template Library](#). Only the class [hed::Dart](#) and the (static) struct [hed::TTLtraits](#) are documented thoroughly. These compounds represent the interface channels between TTL and the application data structure. See [Application Programming Interface to TTL \(API\)](#) for a general documentation of this mechanism. Follow the links to the source code for classes that are not documented in detail - most member functions are self-explanatory.

19.1 The Class Diagram

The classes [hed::Node](#), [hed::Edge](#) and [hed::Triangulation](#) represent the half-edge data structure shown as a class diagram in the figure below. ("Edge" denotes a half-edge). These classes, together with [hed::Dart](#) and [hed::TTLtraits](#) for adaption to TTL, are encapsulated in the namespace **hed**.

Each half-edge has a pointer to the [hed::Node](#) it starts from, a pointer to the next half-edge belonging to the same triangle (counterclockwise), and a pointer to its "twin-edge" belonging to another triangle.

The class [hed::Triangulation](#) contains a list of (half-) edges, each of which represents one triangle in the triangulation. In addition, the class [hed::Triangulation](#) also serves as an interface to the TTL as it implements [hed::TTLtraits::swapEdge](#), [hed::TTLtraits::splitTriangle](#) etc., which are functions required on the application side by function templates in the [TTL](#) (via the traits class).

19.2 Example

Consult the file [main.cpp](#) for a program using TTL and the half-edge data structure.

Chapter 20

GoTools Viewlib

The Viewlib module contains the application 'goview', which is a utility to support visualization of curves, surface, point clouds and line clouds.

goview can read curves and surfaces from an IGES file or from the GoTools internal file format g2 and visualize those. Currently, goview is not able to visualize volumes. In the volume case, it is recommended to pick the boundary surfaces corresponding to the volume and draw them.

For more information on the g2 file format, see [The g2-format, GoTools file format for geometry entities](#).

The program uses Qt for representing the GUI and OpenGL for graphics. Curves and surfaces are tessellated in the submodule tessellate in the module gotools-core. According to their type, curves and surfaces are approximated by triangles or line segments that are convenient for visualization using OpenGL.

The model in the viewer is manipulated using the mouse keys. The left one rotates the model, the middle one is for zooming and the right one for translation of the model.

goview has got a graphical user interface. It has a graphical window, a window containing an object list and a number of pull down menus:

- `file` commands to read and write geometry and to close the current session and make the viewer ready to read a new geometry file.
- `view` options to choose shaded or wire frame mode for visualization. A highlight modus may be toggled and some focusing facilities exist.
- `select` Selection of entities can be done using this menu, in the object list or by using the control key in combination with the left mouse key.
- `group` grouping of objects. This menu is not really used
- `object` this menu offers the possibility to alter the resolution of curves and surfaces and to enable/disable selected entities from the view. Some commands have a key pad short cut.

goview is a utility and not a product. This implies unfortunately that the help functionality is not implemented. Visualization of trimmed surfaces can have some flaws, but they are normally repaired or minimized by increasing the resolution.

20.1 Dependencies

Viewlib requires the following libraries to be installed on the system:

- Qt4, qt.nokia.com
- OpenGL and GLUT, www.opengl.org
- Boost, www.boost.org

Module Index

22.1 Modules

Here is a list of all modules:

RBD common library 157

Chapter 23

Namespace Index

23.1 Namespace List

Here is a list of all namespaces with brief descriptions:

Go	159
Go::AdaptSurface	222
Go::BoundedUtils	224
Go::boxStructuring	233
Go::ClosestPoint	
Namespace for computing closest points	233
Go::cmUtils	
Various utility functions for the compositemodel module	238
Go::CoonsPatchGen	240
Go::CoonsPatchVolumeGen	
This namespace contains functions used to create a Coons Patch volume	247
Go::CreatorsUtils	
Related to the generation of cross tangent curves	249
Go::Curvature	
Curvature analysis related to curves	252
Go::CurvatureAnalysis	253
Go::CurveCreators	255
Go::CurveInterpolator	
Curve interpolation functionality not adapted to the Interpolator class	259
Go::FaceUtilities	259
Go::ftVolumeTools	
This namespace contains service functions related to ftVolume	260
Go::GapRemoval	
Functionality for removal of gaps between two adjacent surfaces of various types	261
Go::GeometryTools	264
Go::HahnsSurfaceGen	276
Go::IntersectionUtils	
Various functions related to the intersection algorithms	278
Go::LinDepUtils	279
Go::LoftSurfaceCreator	
This namespace contains functions used to create lofted surfaces	279
Go::LoftVolumeCreator	
This namespace contains functions used to create lofted volumes	282
Go::LoopUtils	285
Go::LRApproxApp	287

Go::LRBSpline2DUtills	288
Go::LRSplineMBA	289
Go::LRSplineUtills	290
Go::LRSurfStitch	292
Go::Mesh2DUtills	293
Go::ModifySurf	293
Go::OffsetSurfaceUtills	294
Go::OffsetUtills	
Related to the generation of cross tangent curves	295
Go::orientCurves	
Sorts and orients a set of curves	295
Go::Path	
Functions related to sequence of edges	296
Go::PointSetApp	
Point set and triangulation applications	297
Go::qualityUtills	298
Go::RegularizeUtills	
Utility functionality for RegularizeFace and RegularizeFaceSet	298
Go::Singular	302
Go::SplineDebugUtills	302
Go::SplineUtills	304
Go::SplitModelUtills	
Utility functionality for splitting of surface models	309
Go::SurfaceCreators	310
Go::SurfaceInterpolator	
Functionality for creating interpolating surfaces	312
Go::SurfaceModelUtills	
Utility functionality for splitting of surface models	313
Go::SurfaceOnVolumeTools	313
Go::SurfaceTools	
Free functions operating on parametric surfaces	313
Go::TesselatorUtills	
Related to the relative resolution of tessellation	318
Go::tpUtills	318
Go::Utills	
Namespace for some utility functions	319
Go::VolumeInterpolator	
This namespace contains functions used to interpolate a set of points	320
Go::VolumeModelCreator	321
Go::VolumeTools	
This namespace contains free functions operating on parametric volumes	321
hed	327
hetriang	327
NEWMAT	328
RBD_COMMON	335
RBD_LIBRARIES	336
std	336
ttl	
Main interface to TTL	338
ttl_constr	
Constrained Delaunay triangulation	352
ttl_util	
Utilities	353

Chapter 25

Class Index

25.1 Class List

Here are the classes, structs, unions and interfaces with brief descriptions:

Go::AdaptCurve	357
NEWMAT::AddedMatrix	360
Go::AdjacencyInfo	
Struct to store information about adjacency relations between two faces	363
Go::Alg2DElem	365
Go::Alg3DElem	366
Go::AlgObj2DInt	
Class for 2-dimensional algebraic intersection objects	368
Go::AlgObj3DInt	370
Go::AlgObjectInt	374
Go::ApproxCrvToSeqs	375
Go::ApproxCurve	378
Go::ApproxSurf	382
Go::Array< T, Dim >	386
NEWMAT::ArrayLengthSpecifier	394
RBD_COMMON::Bad_alloc	395
NEWMAT::BandLUMatrix	397
NEWMAT::BandMatrix	400
Go::BaryCoordSystem< Dim >	407
Go::BaryCoordSystemTriangle3D	409
RBD_COMMON::BaseException	411
NEWMAT::BaseMatrix	413
Go::BaseSurface	425
Go::BasisDerivs	425
Go::BasisDerivs2	427
Go::BasisDerivsSf	430
Go::BasisDerivsSf2	431
Go::BasisPts	433
Go::BasisPtsSf	434
Go::BdCondFunctor	436
Go::BernsteinMulti	436
Go::BernsteinPoly	446
Go::BernsteinTetrahedralPoly	452
Go::BernsteinTriangularPoly	457
Go::BezierTriangle< N >	
Not documented	462

Go::Binomial	464
Go::BlockBoundaryCondition	466
Go::BlockPointBdCond	469
Go::BlockSolution	470
Go::Body	
A boundary represented solid	474
bool	479
Go::BoundaryFunctionInt	480
Go::BoundaryGeomInt	482
Go::BoundaryIntersectionData	484
Go::BoundedCurve	
A bounded curve. Both parameter values and end points may be given to define the boundaries. Assuming that both points prefer parameter, or both points prefer points. Typically used to bound infinite curves, for instance lines	485
Go::BoundedSurface	494
Go::BoundingBox	515
Go::boxStructuring::BoundingBoxStructure	519
Go::LRSplineSurface::BSKey	522
Go::BsplineBasis	524
Go::CachedInterval	
Helper struct for saving bracketed bounds of influence areas	536
NEWMAT::CannotBuildException	538
Go::CellDivision	539
Go::Circle	
Class that represents a circle. It is a subclass of ElementaryCurve and thus has a parametrization	541
Go::ClosestPointCalculator	552
NEWMAT::ColedMatrix	553
NEWMAT::ColumnVector	555
Go::CompleteEdgeNet	
Complete the edge net of a SurfaceModel . Fetches the wire frame model corresponding to a surface model, and extends it such that the extended wire frame will become the wire frame model corresponding to a volume model have the given surface model as its outer boundary. The extension to the wireframe is represented as pairs of vertices where these vertices lie at the endpoints of the missing edges. NB! This solution is currently not expected to handle all configurations	560
Go::ComplexityInfo	561
Go::CompositeBox	564
Go::CompositeCurve	568
Go::CompositeModel	580
Go::CompositeModelFactory	588
Go::CompositeModelFileHandler	592
Go::CompositeSurface	595
NEWMAT::ConcatenatedMatrix	608
Go::ConcreteCreator< T >	612
Go::Cone	
Class that represents a cone. It is a subclass of ElementarySurface , and thus has a parametrization and is non-selfintersecting	613
Go::ConeVolume	
Class that represents a solid cone. It is a subclass of ElementaryVolume , and has a natural parametrization in terms of a radius u , an angle v , and distance w : $\mathbf{p}(u, v, w) = \mathbf{C} + u (R + w \tan \alpha)((\cos v) \mathbf{x} + (\sin v) \mathbf{y}) + w \mathbf{z}$, where \mathbf{C} is the cone apex, R is the radius when $w = 0$, α is the cone angle, and \mathbf{x} , \mathbf{y} and \mathbf{z} are the (local) axes. The parametrization is bounded by: $0 \leq u \leq 1$, $0 \leq v \leq 2\pi$, $-\infty < w < \infty$. The dimension is 3	626
Go::ConnectionFuncior	633
ControlWord	634
NEWMAT::ConvergenceException	637

Go::CoordinateSystem< Dim >	638
Defines a Cartesian coordinate system	
Go::CPUclock	641
A class for measuring CPU time in programs	
Go::Creator	642
Go::CrossesValue	643
IntersectionPoolUtils. predicate for STL function	
Go::CrossTangentOffset	644
Go::CrossTanOffDist	647
NEWMAT::CroutMatrix	651
Cube	655
Go::CurveBoundedDomain	655
Go::CurveLoop	662
Go::CurveModel	667
Go::CurveOnSurface	675
A curve living on a parametric surface. It either has got information about the curve in geometry space and in the parameter domain of the surface or the ability to compute the other representation given one. The curve may have information on whether it is a constant parameter or boundary curve on the surface	
Go::CurveOnVolume	691
A curve living on a parametric volume. It either has got information about the curve in geometry space and in the parameter domain of the volume or the ability to compute the other representation given one	
CurveResolutionSheet	704
Go::CurveTesselator	705
Go::CvCvIntersector	707
Class that performs intersection between two parametric curves	
Go::CvPtIntersector	711
Go::cvSetConstraint	714
Go::Cylinder	716
Class that represents a cylinder. It is a subclass of ElementarySurface , and thus has a parametrization and is non-selfintersecting	
Go::CylinderInt	729
Class for cylindrical algebraic intersection objects	
Go::CylinderVolume	732
Class that represents a solid cylinder, maybe with empty interior like a straight tube. It is a subclass of ElementaryVolume , and has a natural parametrization in terms of a radius u , an angle v , and distance w : $\mathbf{p}(u, v, w) = \mathbf{C} + u(\cos(v) \mathbf{x} + \sin(v) \mathbf{y}) + w \mathbf{z}$, where \mathbf{C} is a position vector, and \mathbf{x} , \mathbf{y} and \mathbf{z} are the (local) axes. The parametrization is bounded by: $R \leq u \leq S$, $0 \leq v \leq 2\pi$, $-\infty < w < \infty$, where R and S are the inner and outer radius. The dimension is 3	
hed::Dart	739
Dart class for the half-edge data structure	
hetriang::Dart	742
Dart class for the half-edge data structure	
DataHandler	746
DataHandlerVolAndLR	749
DefaultDataHandler	750
Go::ParamSurface::degenerate_info	752
Degeneracy information regarding one boundary surface of the current surface	
Go::DegeneratedIntersectionCurve	754
IntersectionCurve that is degenerated into a single point	
NEWMAT::DiagedMatrix	757
NEWMAT::DiagonalMatrix	759
Dijkstra	764
Go::DirectionCone	768

Go::Disc	
	Class that represents a circular disc. It is a subclass of ElementarySurface , and has a natural parametrization by polar coordinates in terms of a radius r and angle v : $\mathbf{p}(r, v) = \mathbf{C} + r((\cos v) \mathbf{x} + (\sin v) \mathbf{y})$, where \mathbf{C} is the centre position vector and \mathbf{x} and \mathbf{y} are the (local) axes. The parametrization is bounded by: $0 \leq r \leq R$ and $0 \leq v \leq 2\pi$, where R is the disc radius. The dimension is 2 or 3
	771
Go::Domain	782
RBD_COMMON::Domain_error	785
Go::LRSplineSurface::double_pair_hash	786
hed::Edge	
	Edge class in the in the half-edge data structure
	787
hetriang::Edge	
	Edge class in the half-edge data structure
	790
EdgeType	792
Go::EdgeVertex	792
Go::Element2D	796
Go::ElementaryCurve	
	ElementaryCurve is a base class for elementary curves like lines and circles. Such curves have natural parametrizations and ElementaryCurve is therefore a subclass of ParamCurve
	805
Go::ElementarySurface	
	ElementarySurface is a base class for elementary surfaces like planes and cylinders. Such surfaces have natural parametrizations and ElementarySurface is therefore a subclass of ParamSurface . These surfaces are non-self-intersecting
	808
Go::ElementaryVolume	
	ElementaryVolume is a base class for elementary volumes like boxes and solid cylinders. Such volumes have natural parametrizations and ElementaryVolume is therefore a subclass of ParamVolume . These volumes are non-self-intersecting
	814
Go::LRSplineSurface::ElemKey	816
Go::Ellipse	
	Class that represents an ellipse. It is a subclass of ElementaryCurve and thus has a parametrization
	817
Go::EntityList	
	The entity number of all supported IGES entites
	827
Go::Streamable::EofException	829
Go::EvalCurve	829
Go::EvalCurveSet	833
Go::EvalFunctorCurve	836
Go::EvalFunctorSurface	839
Go::EvalOffsetSurface	842
Go::EvalParamCurve	846
Go::EvalSurface	849
Go::FaceAdjacency< edgeType, faceType >	
	Compute adjacency information for a set of surfaces
	852
Go::FaceConnectivity< edgeType >	857
Go::FaceConnectivityUtils< edgeType, faceType >	
	Utilities used in adjacency computations of face sets
	860
Go::FaceSetQuality	861
Go::FaceSetRepair	869
Go::Factorial< N >	
	Compile-time factorial calculations
	871
Go::Factorial< 1 >	872
Go::Factory	873
NEWMAT::FFT_Controller	874
NEWMAT::FindMaximum2	876
NEWMAT::FloatingPointPrecision	
	Floating point precision (type double)
	877
Go::ftCell	
	Helper class handling one of the cells in class CellDivision
	879

Go::ftCellInfo		
Function object for sorting ftCells	881
Go::ftChartSurface	883
Go::ftCurve	888
Go::ftCurveSegment	894
Go::ftEdge		
The ftEdge is a half-edge implementation of a topological data structure	899
Go::ftEdgeBase		
Base class for edges. Defines the interface used in topology analysis	910
Go::ftFaceBase	918
Go::ftGraphEdge	922
Go::ftGroupGeom		
A group of geometrical objects	924
Go::ftLine	926
Go::ftMessage	928
Go::ftPlanarGraph	930
Go::ftPlane	932
Go::ftPoint	934
Go::ftPointSet	937
Go::ftSamplePoint	945
Go::ftSearchNode	951
Go::ftSmoothSurf	952
Go::ftSSfEdge	956
Go::ftSurface	961
Go::ftSurfaceSet	978
Go::ftSurfaceSetPoint	985
Go::ftVolume		
A topological solid with a trivariate geometry description	988
Go::Fun2Fun< Functor >	996
Go::FunctionMinimizer< Functor >	997
GARCH11_LL	1002
NEWMAT::GeneralMatrix	1003
Go::GeneralMesh	1021
NEWMAT::GenericMatrix	1024
Go::GenericTriMesh	1027
Go::GeomObject	1031
Go::GeomObjectInt	1034
Go::GeoTol		
Class handling various tolerances	1034
NEWMAT::GetSubMatrix	1037
Go::go_iterator_traits< literator >	1041
Go::go_iterator_traits< const T * >	1042
Go::go_iterator_traits< T * >	1042
Go::GoTools		
Class containing some service functions for the GoTools "system"	1043
Go::GPos	1045
Go::GpuMatrix< T >	1046
gvActionSheet	1048
gvApplication	1049
gvApplicationVolAndLR	1055
gvCamera	1057
gvColor		
Represents a color by four floats, like in OpenGL	1063
gvCurvePaintable	1064
gvData	1067
gvGenericTriPaintable< FloatType >	1072
gvGenericTriQuadMesh< FloatType >	1074
gvGenericTriQuadPaintable< FloatType >	1076

gvGroup	1078
Structure used to store name and index of members of a group of objects	
gvGroupPropertySheet	1079
gvLineCloudPaintable	1081
gvNoopPaintable	1083
gvObjectList	1085
gvObserver	1087
gvPaintable	1088
gvPainter	
The gvPainter is responsible for painting the 3D scene	1092
gvParametricSurfacePaintable	1094
gvPointCloudPaintable	1096
gvPropertySheet	1100
gvQuadsPaintable	1101
gvRectangularSurfacePaintable	1103
gvRectangularVolumePaintable	1105
gvResolutionDialog	1107
gvStandardMouseHandler	1109
gvTexture	1110
gvView	1112
Handle< T >	
Template class for smart pointers. The actual class must inherit from HandleId	1122
HandleId	
Base class with reference counting for smart pointers	1126
HeapNode	1128
HeapNode2	1130
Go::HermiteAppC	1131
Go::HermiteApprEvalSurf	1133
Go::HermiteAppS	1135
Go::HermiteGrid1D	1136
Go::HermiteGrid1DMulti	1139
Go::HermiteGrid2D	1141
Go::HermiteInterpolator	1144
Go::Hyperbola	
Class that represents a hyperbola. It is a subclass of ElementaryCurve and thus has a parametrization	1147
Go::Identity	
Check coincidence	1157
NEWMAT::IdentityMatrix	1158
Go::IGESconverter	1162
Go::IGESdirentry	
Storage of all data contained in an IGES directory entity	1166
Go::IGESheader	
Storage of all data contained in the IGES header	1168
Go::ImplicitizeCurveAlgo	1172
Go::ImplicitizeCurveAndVectorAlgo	1174
Go::ImplicitizePointCloudAlgo	1177
Go::ImplicitizeSurfaceAlgo	1179
NEWMAT::IncompatibleDimensionsException	1182
NEWMAT::IndexException	1184
Go::IndexMesh2DIterator	1185
Go::IntCrvEvaluator	1187
NEWMAT::InternalException	1190
Go::InterpolatedIntersectionCurve	1192
Go::Interpolator	
Base class for spline interpolators or approximators	1196
Go::IntersectionCurve	1197
Go::IntersectionLink	1203

Go::IntersectionPoint	1205
Go::IntersectionPool	1224
Go::Intersector	1246
Go::Intersector2Obj	1256
Go::IntersectorAlgPar	1263
Go::IntersectorFuncConst	1268
Go::IntPtInfo	1272
Go::IntResultsCompCv	1274
Go::IntResultsModel	1278
Go::IntResultsSfModel	1282
RBD_COMMON::Invalid_argument	1286
Go::InverseFactorial< T, N >	1287
NEWMAT::InvertedMatrix	1288
Go::IsogeometricBlock	1291
Go::IsogeometricModel	1294
Go::IsogeometricSfBlock	1295
Go::IsogeometricSfModel	1299
Go::IsogeometricVolBlock	1301
Go::IsogeometricVolModel	1305
Go::IsoparametricIntersectionCurve	1307
RBD_COMMON::Janitor	1312
NEWMAT::KPMatrix	1314
RBD_COMMON::Length_error	1317
Go::LiftCurve	1319
Go::Line	
Class that represents a line. It is a subclass of ElementaryCurve and thus has a parametrization	1322
Go::Line2DInt	
Class representing an algebraic line in 2-dimensional space	1332
NEWMAT::LinearEquationSolver	1335
Go::LineCloud	1337
Go::LineCloudTesselator	1342
Go::LineStrip	1344
NEWMAT::LL_D_FI	1347
LoadAndStoreFlag	1349
Go::LockedDirDistFunc	1350
NEWMAT::LogAndSign	1351
RBD_COMMON::Logic_error	1353
Go::Loop	
Primarily a loop connected to a face in a boundary represented solid or face set. May also be used to represent a general closed sequence of edges	1354
NEWMAT::LowerBandMatrix	1359
NEWMAT::LowerTriangularMatrix	1364
Go::LRBSpline2D	1368
Go::LRSplineEvalGrid	1376
Go::LRSplineSurface	1379
Go::LRSurfApprox	1398
Go::LRSurfSmoothLS	1405
Go::LSSmoothData	1408
Go::MarchPoint	
Helper class for marching	1414
NEWMAT::MatedMatrix	1416
material_appearance	1418
NEWMAT::Matrix	1420
NEWMAT::MatrixBandWidth	1425
MatrixCol	1427
MatrixColX	1429
NEWMAT::MatrixInput	1431
MatrixRow	1432

MatrixRowCol	1434
NEWMAT::MatrixType	1442
Go::MatrixXD< T, Dim >	1448
Go::Mesh2D	1453
Go::Mesh2DIterator	1457
NEWMAT::MLE_D_FI	1459
Model_3pe	1460
Go::ModelQuality	1462
Go::ModelRepair	1470
MultiDijkstra	1472
NEWMAT::MultipliedMatrix	1476
NEWMAT::MultiRadixCounter	1479
NEWMAT::NegatedMatrix	1480
NEWMAT::NegShiftedMatrix	1483
hed::Node	
Node class for data structures (Inherits from HandleId)	1486
hetriang::Node	
Node class in the half-edge data structure	1489
Go::NonEvaluableIntersectionCurve	
IntersectionCurve that cannot be evaluated	1490
NEWMAT::NonLinearLeastSquares	1494
Go::NoopTesselator	1496
NEWMAT::NotDefinedException	1497
NEWMAT::NotSquareException	1499
NEWMAT::NPDException	1500
NEWMAT::nricMatrix	1502
Go::ObjectHeader	1505
RBD_COMMON::OneDimSolve	1508
RBD_COMMON::Out_of_range	1509
RBD_COMMON::Overflow_error	1511
NEWMAT::OverflowException	1512
Go::Par0FuncIntersector	
This class is performing intersections between two constants	1514
Go::Par1FuncIntersector	1516
Go::Par2FuncIntersector	1519
Go::Parabola	
Class that represents a parabola. It is a subclass of ElementaryCurve and thus has a parametrization	1522
Go::Parallelepiped	
Class that represents a solid parallelepiped. It is a subclass of ElementaryVolume , and thus has a parametrization	1532
Go::Param0FunctionInt	1539
Go::Param1FunctionInt	1548
Go::Param2FunctionInt	1560
Go::ParamCurve	1573
Go::ParamCurveInt	1583
ParametricSurfacePropertySheet	1598
Go::ParametricSurfaceTesselator	1600
Go::ParamFunctionInt	1602
Go::ParamGeomInt	1606
Go::ParamObjectInt	1612
Go::ParamPointInt	1621
Go::ParamSurface	1631
Go::ParamSurfaceInt	1647
Go::ParamVolume	1670
PathType	1676

Go::Plane	
Class that represents a plane. It is a subclass of ElementarySurface , and thus has a parametrization and is non-selfintersecting	1677
Go::PlaneInt	
Class representing planar algebraic intersection objects	1690
Go::Point	1693
Go::PointCloud< Dim >	1702
PointCloudPropertySheet	1707
Go::PointOnCurve	1709
Go::PointOnEdge	1711
Go::PointSequence	1712
PrBiCGStab	1715
PrCellStructure	1718
PrCG	1722
Go::preEvaluationSf	1724
Go::preEvaluationVol	1726
PrExplicitConnectivity	1728
PrFaber_F	1731
PrFastUnorganized_OP	1733
PrFilterbank	1738
PrHeap	1740
PrintCounter	1743
PrLevelTriangulation_OP	1744
PrMat	
This class implements a matrix	1749
PrMatrix	
This class implements a matrix	1752
PrMatSparse	1754
PrNestedNode	1758
PrNestedTriangulation	1762
PrNode	1765
NEWMAT::ProgramException	1768
Go::ProjectCurve	1770
Go::ProjectCurveAndCrossTan	1773
Go::ProjectIntersectionCurve	1777
PrOrganizedPoints	1780
PrParametrizeBdy	1786
PrParametrizeInt	1790
PrParametrizeMesh	1795
PrParamTriangulation	1798
PrPGNode	1802
PrPlanarGraph_OP	1805
PrPrewavelet_F	1809
PrPrmEDDHLS	1811
PrPrmExperimental	1813
PrPrmLeastSquare	1815
PrPrmMeanValue	1816
PrPrmShpPres	1818
PrPrmSurface	1820
PrPrmSymMeanValue	1821
PrPrmUniform	1823
PrPrmWachspress	1824
PrRectangularGrid_OP	1826
PrSubTriangulation	1834
PrThin	1839
PrThreshold	1842
PrTriangle	1845
PrTriangulation_NT	1849

PrTriangulation_OP	1853
PrUnorganized_OP	1860
PrVec	1864
Go::PtPtIntersector	
This class performs intersection between two points	1867
Go::QuadMesh	1871
Go::QualityResults	1874
NEWMAT::R1_Col_I_D	1876
RBD_COMMON::R1_R1	1878
RBD_COMMON::Range_error	1880
rank_info	1882
Go::Rational	1882
Go::raw_pointer_comp< T >	1885
RectangularSurfacePropertySheet	1886
Go::RectangularSurfaceTesselator	1887
RectangularVolumePropertySheet	1890
Go::RectangularVolumeTesselator	1892
Go::RectDomain	1894
Go::RectGrid	1899
Go::RectGridTesselator	1904
RectMatrixCol	1906
RectMatrixDiag	1908
RectMatrixRow	1910
RectMatrixRowCol	1912
Go::LRSplineSurface::Refinement2D	1915
Go::RegistrationInput	
Struct for input to registration, either raw, fine or combined	1916
Go::RegistrationResult	
Struct for result from registration process, either raw, fine or combined	1919
Go::Registrar< T >	1921
Go::RegularizeFace	
Split one face into a number of 4-sided domains without inner trimming. This class is intended for use in block structuring. One face with possible inner and outer trimming is split according to certain rules to result in a face set with 4 sided faces although faces with less than 4 sides can occur. A side is defined as a piece of the face boundary between two corners or between vertices where there are more than one adjacent face. The trimmed surfaces being output from this class can later be approximated by spline surfaces. The splitting procedure is recursive	1922
Go::RegularizeFaceSet	1925
Go::RegularMesh	1927
Go::RegularVolMesh	1931
NEWMAT::ReturnMatrixX	1935
NEWMAT::ReversedMatrix	1937
Go::RotatedBox	1939
Go::RotationInfo	1942
NEWMAT::RowedMatrix	1943
NEWMAT::RowVector	1946
RBD_COMMON::Runtime_error	1950
Go::SamplePointData	
Sample data related to one face. The struct contains one point in a point set with information about position, associated surface normal and curvature. Points lying on the face boundary know about its associated edge. If the surface normal and curvature information regarding boundary points is not unique, the associated data is set to be equal to MAX_DOUBLE	1952
NEWMAT::ScaledMatrix	1954
Go::ScratchVect< T, N >	1957
Go::SecondOrderProperties	1961
Go::SfBoundaryCondition	1963
Go::CompositeModelFileHandler::sfcvinfo	1965
Go::SfCvIntersector	1967

Go::SfPointBdCond	1971
Go::SfPtIntersector	1973
Go::SfSelfIntersector	
This class finds self-intersections for a parametric surface	1976
Go::SfSfIntersector	
This class performs intersection between two parametric surfaces	1981
Go::SfSolution	1987
NEWMAT::ShiftedMatrix	1993
Go::sideConstraint	1996
Go::sideConstraintSet	1997
NEWMAT::SimpleIntArray	1998
Go::SingBox	2001
NEWMAT::SingularException	2002
Go::SingularityInfo	2004
Go::SingUnion	2009
SISLbox	2010
SISLCurve	2011
SISLdir	2013
SISLEdge	2014
SISLIntcurve	2015
SISLIntdat	2017
SISLIntlist	2019
SISLIntpt	2020
SISLIntsurf	2024
SISLObject	2025
SISLPoint	2027
SISLPtedge	2028
SISLSurf	2029
SISLTrack	2032
SISLTrimpar	2034
Go::SmoothCurve	2034
Go::SmoothCurveSet	2037
Go::SmoothSurf	2039
Go::SmoothSurfSet	2050
Go::SmoothTransition	2055
Go::SmoothVolume	
This class modifies a NURBS volume with respect to smoothness, editing constraints and boundary conditions. Specified coefficients are adjusted to minimize a functional combining the different modification conditions	2059
RBD_COMMON::SolutionException	2061
Go::SolveBCG	2063
Go::SolveCG	2064
Go::SolveCGCO	2070
NEWMAT::SolvedMatrix	2071
Go::SpaceIntCrv	2074
Go::Sphere	
Class that represents a sphere. It is a subclass of ElementarySurface , and thus has a parametrization and is non-selfintersecting	2077
Go::SphereInt	
Class representing spherical algebraic intersection objects	2090
Go::SphereVolume	
Class that represents a solid sphere. It is a subclass of ElementaryVolume , and thus has a parametrization	2092
Go::Spline1FunctionInt	2099
Go::Spline2FunctionInt	2104
Go::SplineApproximator	2110

Go::SplineCurve	
SplineCurve	provides methodes for storing, reading and manipulating rational and non-rational
B-spline curves	2113
Go::SplineCurveInt	
Class representing the "intersection object" of a spline curve	2131
SplineCurvePropertySheet	2138
Go::SplineInterpolator	2140
Go::SplineSurface	
SplineSurface	provides methodes for storing, reading and manipulating rational and non-rational
B-spline surfaces	2145
Go::SplineSurfaceInt	2182
Go::SplineVolume	
SplineVolume	provides methodes for storing, reading and manipulating rational and non-rational
B-spline volumes	2193
NEWMAT::SPMatrix	2218
NEWMAT::StackedMatrix	2221
Go::Streamable	2224
NEWMAT::SubMatrixDimensionException	2226
Go::boxStructuring::SubSurfaceBoundingBox	2228
NEWMAT::SubtractedMatrix	2231
Go::LRSplineUtils::support_compare	2233
Go::SurfaceAssembly	2234
Go::boxStructuring::SurfaceData	2236
Go::SurfaceModel	2238
Go::SurfaceOfLinearExtrusion	2267
Go::SurfaceOfRevolution	
Class that represents a surface of revolution. A SurfaceOfRevolution is swept out by a SplineCurve that is rotated around an axis with a complete revolution, and is thereby a parametric surface	2279
Go::SurfaceOnVolume	
A surface living on a parametric volume. It either has got information about the surface in geometry space and in the parameter domain of the volume or both. The surface may have information on whether it is a constant parameter or boundary surface on the volume	2291
SurfaceResolutionSheet	2308
Go::SweepSurfaceCreator	
Functionality to create a spline surface by linear or rotational sweep	2309
Go::SweepVolumeCreator	
Class with static methods for volume creation by sweep methods	2311
NEWMAT::SymmetricBandMatrix	2312
NEWMAT::SymmetricEigenAnalysis	2319
NEWMAT::SymmetricMatrix	2320
Go::Tesselator	2324
TestClass	2325
Go::TestInDomain	
IntersectionPoolUtils. predicate for STL function	2326
time_lapse	2327
Go::Torus	
Class that represents a torus. It is a subclass of ElementarySurface , and thus has a parametrization. A torus may be degenerate. Then the minor radius is greater than the major radius, and it is in principle selfintersecting	2328
Go::TorusVolume	
Class that represents a solid torus, maybe with empty interior like a circular pipe, and/or a section (not full revolution along the main axis). It is a subclass of ElementaryVolume , and has a natural parametrization in terms of a radius u and two angles v and w : $\mathbf{p}(u, v, w) = \mathbf{C} + (R + u \cos w)((\cos v) \mathbf{x} + (\sin v) \mathbf{y}) + (u \sin w) \mathbf{z}$, where \mathbf{C} is a position vector, R is the major radius, and \mathbf{x} , \mathbf{y} and \mathbf{z} are the (local) axes. The parametrization for a full solid torus is bounded by: $0 \leq u \leq r$, $0 \leq v, w \leq 2\pi$, where r is the minor axis. A bended pipe will have a positive minimal limit for u , while a torus segment will have other limits for v . The dimension is 3	2341

Go::tpEdge	2349
Go::tpFace	2355
Go::tpMarchPoint	
Helper class for marching	2357
Go::tpTableEntry< edgeType >	2359
Go::tpTolerances	2360
Go::tpTopologicalInfo	2362
Go::tpTopologyTable< edgeType, faceType >	2363
RBD_COMMON::Tracer	2368
NEWMAT::TransposedMatrix	2370
Go::Triangle	2372
hetriang::Triangulation	
Triangulation class for the half-edge data structure with adaption to TTL	2373
hed::Triangulation	
Triangulation class for the half-edge data structure with adaption to TTL	2376
Go::TrimCurve	2381
Go::ttlPoint	2384
hed::TTLtraits	
Traits class (static struct) for the half-edge data structure	2386
hetriang::TTLtraits	
Traits class (static struct) for the half-edge data structure	2389
UnfNodeType	2393
Go::CoonsPatchGen::UnKnownError	
Exception class	2394
NEWMAT::UpperBandMatrix	2395
NEWMAT::UpperTriangularMatrix	2399
vector3t< T >	2403
NEWMAT::VectorException	2411
Go::Vertex	
The vertex class represents the vertex entity in a boundary represented solid or face set	2413
Go::VolBoundaryCondition	2420
Go::VolPointBdCond	2422
Go::VolSolution	2424
Go::VolumeAdjacency	
Adjacency analysis of volume models	2429
Go::VolumeAdjacencyInfo	
Struct to store information about adjacency relations between two bodies	2431
Go::VolumeModel	
A set of volumes including topology information	2434
Go::VolumeModelFileHandler	2444
Go::VolumeParameterCurve	
An evaluator based curve representing the parameter domain curve in a given volume which represents the same curve as a given space curve. Project a geometry curve into the parameter domain of a volume	2445
Go::VolumeSpaceCurve	
An evaluator based curve representing the space curve corresponding to parameter domain curve in a given volume. Compute the space curve corresponding to a curve in the parameter domain of a volume	2449
Go::Zero_Parameter_Span_Error	
Error object used internally in IntersectionCurve	2452

Chapter 26

File Index

26.1 File List

Here is a list of all files with brief descriptions:

compositemodel/include/GoTools/compositemodel/AdaptSurface.h	2453

27.1.1 Detailed Description

27.1.2 Macro Definition Documentation

27.1.2.1 `#define` ATandT

Definition at line 277 of file [include.h](#).

27.1.2.2 #define bool_LIB 0

Definition at line 34 of file include.h.

27.1.2.3 #define DEFAULT_HEADER

Definition at line 105 of file include.h.

27.1.2.4 #define TypeDefException

Definition at line 47 of file include.h.

27.1.2.5 #define use_namespace

Definition at line 10 of file include.h.

27.1.2.6 #define UseExceptions

Definition at line 19 of file include.h.

27.1.2.7 #define USING_DOUBLE

Definition at line 31 of file include.h.

Chapter 28

Namespace Documentation

28.1 Go Namespace Reference

Namespaces

- [AdaptSurface](#)
- [BoundedUtils](#)
- [boxStructuring](#)
- [ClosestPoint](#)

Namespace for computing closest points.

- [cmUtils](#)

Various utility functions for the compositemodel module.

- [CoonsPatchGen](#)
- [CoonsPatchVolumeGen](#)

This namespace contains functions used to create a Coons Patch volume.

- [CreatorsUtils](#)

Related to the generation of cross tangent curves.

- [Curvature](#)

Curvature analysis related to curves.

- [CurvatureAnalysis](#)
- [CurveCreators](#)
- [CurveInterpolator](#)

Curve interpolation functionality not adapted to the [Interpolator](#) class.

- [FaceUtilities](#)
- [ftVolumeTools](#)

This namespace contains service functions related to [ftVolume](#).

- [GapRemoval](#)

Functionality for removal of gaps between two adjacent surfaces of various types.

- [GeometryTools](#)
- [HahnsSurfaceGen](#)
- [IntersectionUtils](#)

Various functions related to the intersection algorithms.

- [LinDepUtils](#)
- [LoftSurfaceCreator](#)

This namespace contains functions used to create lofted surfaces.

- [LoftVolumeCreator](#)

This namespace contains functions used to create lofted volumes.

- [LoopUtils](#)
- [LRApproxApp](#)
- [LRBSpline2DUtills](#)
- [LRSplineMBA](#)
- [LRSplineUtills](#)
- [LRSurfStitch](#)
- [Mesh2DUtills](#)
- [ModifySurf](#)
- [OffsetSurfaceUtills](#)
- [OffsetUtills](#)

Related to the generation of cross tangent curves.

- [orientCurves](#)

Sorts and orients a set of curves.

- [Path](#)

Functions related to sequence of edges.

- [PointSetApp](#)

Point set and triangulation applications.

- [qualityUtills](#)
- [RegularizeUtills](#)

Utility functionality for [RegularizeFace](#) and [RegularizeFaceSet](#).

- [Singular](#)
- [SplineDebugUtills](#)
- [SplineUtills](#)
- [SplitModelUtills](#)

Utility functionality for splitting of surface models.

- [SurfaceCreators](#)
- [SurfaceInterpolator](#)

Functionality for creating interpolating surfaces.

- [SurfaceModelUtills](#)

Utility functionality for splitting of surface models.

- [SurfaceOnVolumeTools](#)
- [SurfaceTools](#)

Free functions operating on parametric surfaces.

- [TesselatorUtills](#)

Related to the relative resolution of tessellation.

- [tpUtills](#)
- [Utills](#)

Namespace for some utility functions.

- [VolumeInterpolator](#)

This namespace contains functions used to interpolate a set of points.

- [VolumeModelCreator](#)
- [VolumeTools](#)

This namespace contains free functions operating on parametric volumes.

Classes

- class [AdaptCurve](#)
- struct [AdjacencyInfo](#)
 - Struct to store information about adjacency relations between two faces.*
- struct [Alg2DElem](#)
- struct [Alg3DElem](#)
- class [AlgObj2DInt](#)
 - Class for 2-dimensional algebraic intersection objects.*
- class [AlgObj3DInt](#)
- class [AlgObjectInt](#)
- class [ApproxCrvToSeqs](#)
- class [ApproxCurve](#)
- class [ApproxSurf](#)
- class [Array](#)
- class [BaryCoordSystem](#)
- class [BaryCoordSystemTriangle3D](#)
- class [BaseSurface](#)
- struct [BasisDerivs](#)
- struct [BasisDerivs2](#)
- struct [BasisDerivsSf](#)
- struct [BasisDerivsSf2](#)
- struct [BasisPts](#)
- struct [BasisPtsSf](#)
- class [BdCondFunctor](#)
- class [BernsteinMulti](#)
- class [BernsteinPoly](#)
- class [BernsteinTetrahedralPoly](#)
- class [BernsteinTriangularPoly](#)
- class [BezierTriangle](#)
 - Not documented.*
- class [Binomial](#)
- class [BlockBoundaryCondition](#)
- class [BlockPointBdCond](#)
- class [BlockSolution](#)
- class [Body](#)
 - A boundary represented solid.*
- struct [BoundaryFunctionInt](#)
- struct [BoundaryGeomInt](#)
- struct [BoundaryIntersectionData](#)
- class [BoundedCurve](#)
 - A bounded curve. Both parameter values and end points may be given to define the boundaries. Assuming that both points prefer parameter, or both points prefer points. Typically used to bound infinite curves, for instance lines.*
- class [BoundedSurface](#)
- class [BoundingBox](#)
- class [BsplineBasis](#)
- struct [CachedInterval](#)
 - Helper struct for saving bracketed bounds of influence areas.*
- class [CellDivision](#)
- class [Circle](#)
 - Class that represents a circle. It is a subclass of [ElementaryCurve](#) and thus has a parametrization.*
- class [ClosestPointCalculator](#)
- class [CompleteEdgeNet](#)

Complete the edge net of a [SurfaceModel](#). Fetches the wire frame model corresponding to a surface model, and extends it such that the extended wire frame will become the wire frame model corresponding to a volume model have the given surface model as its outer boundary. The extension to the wireframe is represented as pairs of vertices where these vertices lie at the endpoints of the missing edges. NB! This solution is currently not expected to handle all configurations.

- class [ComplexityInfo](#)
- class [CompositeBox](#)
- class [CompositeCurve](#)
- class [CompositeModel](#)
- class [CompositeModelFactory](#)
- class [CompositeModelFileHandler](#)
- class [CompositeSurface](#)
- class [ConcreteCreator](#)
- class [Cone](#)

Class that represents a cone. It is a subclass of [ElementarySurface](#), and thus has a parametrization and is non-selfintersecting.

- class [ConeVolume](#)

Class that represents a solid cone. It is a subclass of [ElementaryVolume](#), and has a natural parametrization in terms of a radius u , an angle v , and distance w : $\mathbf{p}(u, v, w) = \mathbf{C} + u(R + w \tan \alpha)((\cos v) \mathbf{x} + (\sin v) \mathbf{y}) + w \mathbf{z}$, where \mathbf{C} is the cone apex, R is the radius when $w = 0$, α is the cone angle, and \mathbf{x} , \mathbf{y} and \mathbf{z} are the (local) axes. The parametrization is bounded by: $0 \leq u \leq 1, 0 \leq v \leq 2\pi, -\infty < w < \infty$. The dimension is 3.

- class [ConnectionFunctor](#)
- class [CoordinateSystem](#)

Defines a Cartesian coordinate system.

- class [CPUclock](#)

A class for measuring CPU time in programs.

- class [Creator](#)
- class [CrossesValue](#)

[IntersectionPoolUtils](#). predicate for STL function.

- class [CrossTangentOffset](#)
- class [CrossTanOffDist](#)
- class [CurveBoundedDomain](#)
- class [CurveLoop](#)
- class [CurveModel](#)
- class [CurveOnSurface](#)

A curve living on a parametric surface. It either has got information about the curve in geometry space and in the parameter domain of the surface or the ability to compute the other representation given one. The curve may have information on whether it is a constant parameter or boundary curve on the surface.

- class [CurveOnVolume](#)

A curve living on a parametric volume. It either has got information about the curve in geometry space and in the parameter domain of the volume or the ability to compute the other representation given one.

- class [CurveTesselator](#)
- class [CvCvIntersector](#)

Class that performs intersection between two parametric curves.

- class [CvPtIntersector](#)
- struct [cvSetConstraint](#)
- class [Cylinder](#)

Class that represents a cylinder. It is a subclass of [ElementarySurface](#), and thus has a parametrization and is non-selfintersecting.

- class [CylinderInt](#)

Class for cylindrical algebraic intersection objects.

- class [CylinderVolume](#)

Class that represents a solid cylinder, maybe with empty interior like a straight tube. It is a subclass of [ElementaryVolume](#), and has a natural parametrization in terms of a radius u , an angle v , and distance w : $\mathbf{p}(u, v, w) = \mathbf{C} + u(\cos(v) \mathbf{x} + \sin(v) \mathbf{y}) + w \mathbf{z}$, where \mathbf{C} is a position vector, and \mathbf{x} , \mathbf{y} and \mathbf{z} are the (local) axes. The parametrization is bounded by: $R \leq u \leq S, 0 \leq v \leq 2\pi, -\infty < w < \infty$, where R and S are the inner and outer radius. The dimension is 3.

- class [DegeneratedIntersectionCurve](#)
IntersectionCurve that is degenerated into a single point.
- class [DirectionCone](#)
- class [Disc](#)
Class that represents a circular disc. It is a subclass of [ElementarySurface](#), and has a natural parametrization by polar coordinates in terms of a radius r and angle v : $\mathbf{p}(r, v) = \mathbf{C} + r((\cos v) \mathbf{x} + (\sin v) \mathbf{y})$, where \mathbf{C} is the centre position vector and \mathbf{x} and \mathbf{y} are the (local) axes. The parametrization is bounded by: $0 \leq r \leq R$ and $0 \leq v \leq 2\pi$, where R is the disc radius. The dimension is 2 or 3.
- class [Domain](#)
- class [EdgeVertex](#)
- class [Element2D](#)
- class [ElementaryCurve](#)
ElementaryCurve is a base class for elementary curves like lines and circles. Such curves have natural parametrizations and *ElementaryCurve* is therefore a subclass of [ParamCurve](#).
- class [ElementarySurface](#)
ElementarySurface is a base class for elementary surfaces like planes and cylinders. Such surfaces have natural parametrizations and *ElementarySurface* is therefore a subclass of [ParamSurface](#). These surfaces are non-self-intersecting.
- class [ElementaryVolume](#)
ElementaryVolume is a base class for elementary volumes like boxes and solid cylinders. Such volumes have natural parametrizations and *ElementaryVolume* is therefore a subclass of [ParamVolume](#). These volumes are non-self-intersecting.
- class [Ellipse](#)
Class that represents an ellipse. It is a subclass of [ElementaryCurve](#) and thus has a parametrization.
- struct [EntityList](#)
The entity number of all supported IGES entites.
- class [EvalCurve](#)
- class [EvalCurveSet](#)
- class [EvalFunctorCurve](#)
- class [EvalFunctorSurface](#)
- class [EvalOffsetSurface](#)
- class [EvalParamCurve](#)
- class [EvalSurface](#)
- class [FaceAdjacency](#)
Compute adjacency information for a set of surfaces.
- struct [FaceConnectivity](#)
- class [FaceConnectivityUtils](#)
Utilities used in adjacency computations of face sets.
- class [FaceSetQuality](#)
- class [FaceSetRepair](#)
- struct [Factorial](#)
Compile-time factorial calculations.
- struct [Factorial< 1 >](#)
- class [Factory](#)
- class [ftCell](#)
Helper class handling one of the cells in class [CellDivision](#).
- class [ftCellInfo](#)
Function object for sorting [ftCells](#).
- class [ftChartSurface](#)
- class [ftCurve](#)
- class [ftCurveSegment](#)
- class [ftEdge](#)
The [ftEdge](#) is a half-edge implementation of a topological data structure.
- class [ftEdgeBase](#)

Base class for edges. Defines the interface used in topology analysis.

- class [ftFaceBase](#)
- class [ftGraphEdge](#)
- class [ftGroupGeom](#)

A group of geometrical objects.

- class [ftLine](#)
- class [ftMessage](#)
- class [ftPlanarGraph](#)
- class [ftPlane](#)
- class [ftPoint](#)
- class [ftPointSet](#)
- class [ftSamplePoint](#)
- class [ftSearchNode](#)
- class [ftSmoothSurf](#)
- class [ftSSfEdge](#)
- class [ftSurface](#)
- class [ftSurfaceSet](#)
- class [ftSurfaceSetPoint](#)
- class [ftVolume](#)

A topological solid with a trivariate geometry description.

- class [Fun2Fun](#)
- class [FunctionMinimizer](#)
- class [GeneralMesh](#)
- class [GenericTriMesh](#)
- class [GeomObject](#)
- class [GeomObjectInt](#)
- class [GeoTol](#)

Class handling various tolerances.

- struct [go_iterator_traits](#)
- struct [go_iterator_traits< const T * >](#)
- struct [go_iterator_traits< T * >](#)
- class [GoTools](#)

Class containing some service functions for the [GoTools](#) "system".

- struct [GPos](#)
- class [GpuMatrix](#)
- class [HermiteAppC](#)
- class [HermiteApprEvalSurf](#)
- class [HermiteAppS](#)
- class [HermiteGrid1D](#)
- class [HermiteGrid1DMulti](#)
- class [HermiteGrid2D](#)
- class [HermiteInterpolator](#)
- class [Hyperbola](#)

Class that represents a hyperbola. It is a subclass of [ElementaryCurve](#) and thus has a parametrization.

- class [Identity](#)

Check coincidence.

- class [IGESconverter](#)
- struct [IGESdirentry](#)

Storage of all data contained in an IGES directory entity.

- struct [IGESheader](#)

Storage of all data contained in the IGES header.

- class [ImplicitizeCurveAlgo](#)
- class [ImplicitizeCurveAndVectorAlgo](#)

- class [ImplicitizePointCloudAlgo](#)
- class [ImplicitizeSurfaceAlgo](#)
- class [IndexMesh2DIterator](#)
- class [IntCrvEvaluator](#)
- class [InterpolatedIntersectionCurve](#)
- class [Interpolator](#)

Base class for spline interpolators or approximators.

- class [IntersectionCurve](#)
- class [IntersectionLink](#)
- class [IntersectionPoint](#)
- class [IntersectionPool](#)
- class [Intersector](#)
- class [Intersector2Obj](#)
- class [IntersectorAlgPar](#)
- class [IntersectorFuncConst](#)
- struct [IntPtInfo](#)
- class [IntResultsCompCv](#)
- class [IntResultsModel](#)
- class [IntResultsSfModel](#)
- struct [InverseFactorial](#)
- class [IsogeometricBlock](#)
- class [IsogeometricModel](#)
- class [IsogeometricSfBlock](#)
- class [IsogeometricSfModel](#)
- class [IsogeometricVolBlock](#)
- class [IsogeometricVolModel](#)
- class [IsoparametricIntersectionCurve](#)
- class [LiftCurve](#)
- class [Line](#)

Class that represents a line. It is a subclass of [ElementaryCurve](#) and thus has a parametrization.

- class [Line2DInt](#)

Class representing an algebraic line in 2-dimensional space.

- class [LineCloud](#)
- class [LineCloudTesselator](#)
- class [LineStrip](#)
- class [LockedDirDistFunc](#)
- class [Loop](#)

Primarily a loop connected to a face in a boundary represented solid or face set. May also be used to represent a general closed sequence of edges.

- class [LRBSpline2D](#)
- class [LRSplineEvalGrid](#)
- class [LRSplineSurface](#)
- class [LRSurfApprox](#)
- class [LRSurfSmoothLS](#)
- struct [LSSmoothData](#)
- class [MarchPoint](#)

Helper class for marching.

- class [MatrixXD](#)
- class [Mesh2D](#)
- class [Mesh2DIterator](#)
- class [ModelQuality](#)
- class [ModelRepair](#)
- class [NonEvaluableIntersectionCurve](#)

[IntersectionCurve](#) that cannot be evaluated.

- class [NoopTesselator](#)
- class [ObjectHeader](#)
- class [Par0FuncIntersector](#)

This class is performing intersections between two constants.

- class [Par1FuncIntersector](#)
- class [Par2FuncIntersector](#)
- class [Parabola](#)

Class that represents a parabola. It is a subclass of [ElementaryCurve](#) and thus has a parametrization.

- class [Parallelepiped](#)

Class that represents a solid parallelepiped. It is a subclass of [ElementaryVolume](#), and thus has a parametrization.

- class [Param0FunctionInt](#)
- class [Param1FunctionInt](#)
- class [Param2FunctionInt](#)
- class [ParamCurve](#)
- class [ParamCurveInt](#)
- class [ParametricSurfaceTesselator](#)
- class [ParamFunctionInt](#)
- class [ParamGeomInt](#)
- class [ParamObjectInt](#)
- class [ParamPointInt](#)
- class [ParamSurface](#)
- class [ParamSurfaceInt](#)
- class [ParamVolume](#)
- class [Plane](#)

Class that represents a plane. It is a subclass of [ElementarySurface](#), and thus has a parametrization and is non-selfintersecting.

- class [PlaneInt](#)

Class representing planar algebraic intersection objects.

- class [Point](#)
- class [PointCloud](#)
- class [PointOnCurve](#)
- class [PointOnEdge](#)
- class [PointSequence](#)
- struct [preEvaluationSf](#)
- struct [preEvaluationVol](#)
- class [ProjectCurve](#)
- class [ProjectCurveAndCrossTan](#)
- class [ProjectIntersectionCurve](#)
- class [PtPtIntersector](#)

This class performs intersection between two points.

- class [QuadMesh](#)
- class [QualityResults](#)
- class [Rational](#)
- struct [raw_pointer_comp](#)
- class [RectangularSurfaceTesselator](#)
- class [RectangularVolumeTesselator](#)
- class [RectDomain](#)
- class [RectGrid](#)
- class [RectGridTesselator](#)
- struct [RegistrationInput](#)

Struct for input to registration, either raw, fine or combined.

- struct [RegistrationResult](#)

Struct for result from registration process, either raw, fine or combined.

- class [Registrar](#)
- class [RegularizeFace](#)

Split one face into a number of 4-sided domains without inner trimming. This class is intended for use in block structuring. One face with possible inner and outer trimming is split according to certain rules to result in a face set with 4 sided faces although faces with less than 4 sides can occur. A side is defined as a piece of the face boundary between two corners or between vertices where there are more than one adjacent face. The trimmed surfaces being output from this class can later be approximated by spline surfaces. The splitting procedure is recursive.
- class [RegularizeFaceSet](#)
- class [RegularMesh](#)
- class [RegularVolMesh](#)
- class [RotatedBox](#)
- struct [RotationInfo](#)
- struct [SamplePointData](#)

Sample data related to one face. The struct contains one point in a point set with information about position, associated surface normal and curvature. Points lying on the face boundary know about its associated edge. If the surface normal and curvature information regarding boundary points is not unique, the associated data is set to be equal to MAX_DOUBLE.
- class [ScratchVect](#)
- struct [SecondOrderProperties](#)
- class [SfBoundaryCondition](#)
- class [SfCvIntersector](#)
- class [SfPointBdCond](#)
- class [SfPtIntersector](#)
- class [SfSelfIntersector](#)

This class finds self-intersections for a parametric surface.
- class [SfSfIntersector](#)

This class performs intersection between two parametric surfaces.
- class [SfSolution](#)
- struct [sideConstraint](#)
- struct [sideConstraintSet](#)
- struct [SingBox](#)
- class [SingularityInfo](#)
- struct [SingUnion](#)
- class [SmoothCurve](#)
- class [SmoothCurveSet](#)
- class [SmoothSurf](#)
- class [SmoothSurfSet](#)
- class [SmoothTransition](#)
- class [SmoothVolume](#)

This class modifies a NURBS volume with respect to smoothness, editing constraints and boundary conditions. Specified coefficients are adjusted to minimize a functional combining the different modification conditions.
- class [SolveBCG](#)
- class [SolveCG](#)
- class [SolveCGCO](#)
- class [SpaceIntCrv](#)
- class [Sphere](#)

Class that represents a sphere. It is a subclass of [ElementarySurface](#), and thus has a parametrization and is non-selfintersecting.
- class [SphereInt](#)

Class representing spherical algebraic intersection objects.
- class [SphereVolume](#)

Class that represents a solid sphere. It is a subclass of [ElementaryVolume](#), and thus has a parametrization.
- class [Spline1FunctionInt](#)
- class [Spline2FunctionInt](#)
- class [SplineApproximator](#)

- class [SplineCurve](#)
SplineCurve provides methodes for storing, reading and manipulating rational and non-rational B-spline curves.
- class [SplineCurveInt](#)
Class representing the "intersection object" of a spline curve.
- class [SplineInterpolator](#)
- class [SplineSurface](#)
SplineSurface provides methodes for storing, reading and manipulating rational and non-rational B-spline surfaces.
- class [SplineSurfaceInt](#)
- class [SplineVolume](#)
SplineVolume provides methodes for storing, reading and manipulating rational and non-rational B-spline volumes.
- class [Streamable](#)
- class [SurfaceAssembly](#)
- class [SurfaceModel](#)
- class [SurfaceOfLinearExtrusion](#)
- class [SurfaceOfRevolution](#)
Class that represents a surface of revolution. A [SurfaceOfRevolution](#) is swept out by a [SplineCurve](#) that is rotated around an axis with a complete revolution, and is thereby a parametric surface.
- class [SurfaceOnVolume](#)
A surface living on a parametric volume. It either has got information about the surface in geometry space and in the parameter domain of the volume or both. The surface may have information on whether it is a constant parameter or boundary surface on the volume.
- class [SweepSurfaceCreator](#)
Functionality to create a spline surface by linear or rotational sweep.
- class [SweepVolumeCreator](#)
Class with static methods for volume creation by sweep methods.
- class [Tesselator](#)
- class [TestInDomain](#)
IntersectionPoolUtils. predicate for STL function.
- class [Torus](#)
Class that represents a torus. It is a subclass of [ElementarySurface](#), and thus has a parametrization. A torus may be degenerate. Then the minor radius is greater than the major radius, and it is in principle selfintersecting.
- class [TorusVolume](#)
Class that represents a solid torus, maybe with empty interior like a circular pipe, and/or a section (not full revolution along the main axis). It is a subclass of [ElementaryVolume](#), and has a natural parametrization in terms of a radius u and two angles v and w : $\mathbf{p}(u, v, w) = \mathbf{C} + (R + u \cos w)((\cos v) \mathbf{x} + (\sin v) \mathbf{y}) + (u \sin w) \mathbf{z}$, where \mathbf{C} is a position vector, R is the major radius, and \mathbf{x} , \mathbf{y} and \mathbf{z} are the (local) axes. The parametrization for a full solid torus is bounded by: $0 \leq u \leq r$, $0 \leq v, w \leq 2\pi$, where r is the minor axis. A bended pipe will have a positive minimal limit for u , while a torus segment will have other limits for v . The dimension is 3.
- class [tpEdge](#)
- class [tpFace](#)
- class [tpMarchPoint](#)
Helper class for marching.
- class [tpTableEntry](#)
- struct [tpTolerances](#)
- struct [tpTopologicalInfo](#)
- class [tpTopologyTable](#)
- class [Triangle](#)
- class [TrimCurve](#)
- class [ttlPoint](#)
- class [Vertex](#)
The vertex class represents the vertex entity in a boundary represented solid or face set.
- class [VolBoundaryCondition](#)
- class [VolPointBdCond](#)
- class [VolSolution](#)

- class [VolumeAdjacency](#)
Adjacency analysis of volume models.
- struct [VolumeAdjacencyInfo](#)
Struct to store information about adjacency relations between two bodies.
- class [VolumeModel](#)
A set of volumes including topology information.
- class [VolumeModelFileHandler](#)
- class [VolumeParameterCurve](#)
An evaluator based curve representing the parameter domain curve in a given volume which represents the same curve as a given space curve. Project a geometry curve into the parameter domain of a volume.
- class [VolumeSpaceCurve](#)
An evaluator based curve representing the space curve corresponding to parameter domain curve in a given volume. Compute the space curve corresponding to a curve in the parameter domain of a volume.
- class [Zero_Parameter_Span_Error](#)
Error object used internally in [IntersectionCurve](#).

Typedefs

- typedef `std::vector< ftSearchNode >::iterator` [GraphIter](#)
- typedef `std::list< shared_ptr< ftSamplePoint > >` [PointList](#)
- typedef `ftSamplePoint *` [PointIter](#)
- typedef `std::pair< std::pair< double, double >, std::pair< ftFaceBase *, int > >` [BoundaryPiece](#)
- typedef struct [Go::sideConstraint](#) [sideConstraint](#)
- typedef struct [Go::sideConstraintSet](#) [sideConstraintSet](#)
- typedef `PointCloud< 3 >` [PointCloud3D](#)
- typedef `PointCloud< 4 >` [PointCloud4D](#)
- typedef `Array< double, 2 >` [Vector2D](#)
Typedef for ease of use in frequently used case.
- typedef `Array< double, 3 >` [Vector3D](#)
Typedef for ease of use in frequently used case.
- typedef `Array< double, 4 >` [Vector4D](#)
Typedef for ease of use in frequently used case.
- typedef `BaryCoordSystem< 2 >` [BaryCoordSystem2D](#)
- typedef `BaryCoordSystem< 3 >` [BaryCoordSystem3D](#)
- typedef `Element2D simpleElement`
- typedef `std::map< LRBSpline2D *, size_t >` [BsplineIndexMap](#)

- `const int MINOR_VERSION = 0`

### 28.1.1 Detailed Description

The [Go](#) namespace is the common namespace for all [GoTools](#) modules.

### 28.1.2 Typedef Documentation

#### 28.1.2.1 `typedef BaryCoordSystem<2> Go::BaryCoordSystem2D`

Definition at line 183 of file `BaryCoordSystem.h`.

#### 28.1.2.2 `typedef BaryCoordSystem<3> Go::BaryCoordSystem3D`

Definition at line 184 of file `BaryCoordSystem.h`.

#### 28.1.2.3 `typedef std::pair<std::pair<double, double>, std::pair<ftFaceBase*, int> > Go::BoundaryPiece`

Definition at line 45 of file `ftSurfaceSet.h`.

#### 28.1.2.4 `typedef std::map<LRBSpline2D*, size_t> Go::BsplineIndexMap`

This class modifies a LR spline surface with respect to conditions on smoothness, data points and boundary conditions.

Definition at line 70 of file `LRSurfSmoothLS.h`.

#### 28.1.2.5 `typedef std::vector<ftSearchNode>::iterator Go::GraphIter`

Definition at line 29 of file `ftPlanarGraph.h`.

#### 28.1.2.6 `typedef PointCloud<3> Go::PointCloud3D`

Definition at line 261 of file `PointCloud.h`.

**28.1.2.7 typedef PointCloud<4> Go::PointCloud4D**

Definition at line 262 of file PointCloud.h.

**28.1.2.8 typedef ftSamplePoint\* Go::PointIter**

Definition at line 63 of file ftPointSet.h.

**28.1.2.9 typedef std::list<shared\_ptr<ftSamplePoint> > Go::PointList**

Definition at line 59 of file ftPointSet.h.

**28.1.2.10 typedef struct Go::sideConstraint Go::sideConstraint**

Struct defining linear side constraints between control points in a surface. The elements of `factor_` correspond to a linear combination of control points on the left side of the equation, whilst `constant_term_` denotes the right side of the equation.

**28.1.2.11 typedef struct Go::sideConstraintSet Go::sideConstraintSet**

Struct defining linear side constraints between control points in a set of surfaces. The elements of `factor_` correspond to a linear combination of control points on the left side of the equation, whilst `constant_term_` denotes the right side of the equation.

**28.1.2.12 typedef Element2D Go::simpleElement**

Definition at line 66 of file LRSplineEvalGrid.h.

**28.1.2.13 typedef Array<double, 2> Go::Vector2D**

Typedef for ease of use in frequently used case.

Definition at line 431 of file Array.h.

**28.1.2.14 typedef Array<double, 3> Go::Vector3D**

Typedef for ease of use in frequently used case.

Definition at line 433 of file Array.h.

**28.1.2.15 typedef Array<double, 4> Go::Vector4D**

Typedef for ease of use in frequently used case.

Definition at line 435 of file Array.h.

### 28.1.3 Enumeration Type Documentation

#### 28.1.3.1 anonymous enum

Enumeration of various pretopologies that can be associated with intersections.

Enumerator

***pretop\_UNDEF***  
***pretop\_IN***  
***pretop\_OUT***  
***pretop\_ON***  
***pretop\_AT***

Definition at line 56 of file GoIntersections.h.

#### 28.1.3.2 enum Go::AlgorithmChoice

This enumeration denotes whether the 'closestPtSurfSurfPlane' function should base itself upon a geometrical algorithm (marching on the surfaces) or a pure functional one (constrained minimization of a cost function). The default has been set to FUNCTIONAL, as there are flaws in the GEOMETRICAL one when it comes to close-to-degenerate cases.

Enumerator

***GEOMETRICAL***  
***FUNCTIONAL***

Definition at line 56 of file ClosestPoint.h.

#### 28.1.3.3 enum Go::BdConditionType

Enumerator

***UNKNOWN***  
***ZERO\_DIRICHLET***  
***CONSTANT\_DIRICHLET***  
***DIRICHLET***  
***ZERO\_NEUMANN***  
***NEUMANN***  
***SYMMETRY***

Definition at line 48 of file BdConditionType.h.

#### 28.1.3.4 enum Go::ClassType

All concrete classes that inherit [GeomObject](#) should have a matching enum in ClassType. It is necessary to have a central location for the type identification numbers, so that two classes in different modules (for example) does not try to use the same number. At the same time, it is something we'd like to avoid, because it forces you to update this file every time you add a new GeomObject- inheriting class.

If you need to add a new type, you may also need to add a "Registrar", see the '[GoTools](#)' class. If the new class is part of 'geometry' in 'gotools-core', do this in the init() function of the [GoTools](#) class itself. If it's outside the core, then write another class with its own static init() function containing the [Registrar](#).

Also, if you need the name of that added type, i.e. a ClassType-to-string conversion, then you should add that as well. See [GoTools::className\(\)](#).

Enumerator

**go**  
**disp**  
**IGES**

Definition at line 74 of file IGESconverter.h.

## 28.1.3.11 enum Go::ftCurveType

Indicates type of curve described by a [ftCurve](#).

Enumerator

**CURVE\_NOTYPE** Untyped curve.  
**CURVE\_INTERSECTION** Curve mostly in interior of surfaces.  
**CURVE\_EDGE** Curve lying on the edge of surfaces.  
**CURVE\_KINK** Between surfaces joined by kink.  
**CURVE\_CORNER** Between surfaces meeting at a corner line.  
**CURVE\_GAP** Between surfaces joined by gap.  
**CURVE\_SINGULAR** Curve mostly in interior of one surface.

Definition at line 57 of file ftCurve.h.

## 28.1.3.12 enum Go::ftmessages

Enumerator

*FT\_NOT\_IMPLEMENTED*  
*FT\_NO\_DATA*  
*FT\_BAD\_INPUT\_FILE*  
*FT\_ERROR\_IN\_READ\_IGES*  
*FT\_DISCONTINUITY*  
*FT\_UNEXPECTED\_DATA\_TYPE*  
*FT\_NON\_4\_SIDED\_SURF*  
*FT\_WRONG\_NO\_OF\_BOUNDARIES*  
*FT\_INSUFFICIENT\_MESH\_CURVES*  
*FT\_ERROR\_IN\_TOPOLOGY\_ANALYSIS*  
*FT\_TOPOLOGY\_PROBLEM*  
*FT\_ERROR\_IN\_SURFACE\_CREATION*  
*FT\_ERROR\_IN\_PARAMETERIZE*  
*FT\_ERROR\_IN\_SURFACE\_TRIMMING*  
*FT\_NOT\_SUPPORTED*  
*FT\_NOT\_SPLINE\_SURF*  
*FT\_ERROR\_IN\_SURFACE\_GRIDDING*  
*FT\_NEIGHBOUR\_GRID\_SIZE\_DIFFER*  
*FT\_OK*  
*FT\_APPROX\_ERROR\_TOO\_LARGE*  
*FT\_COULD\_NOT\_REFINE\_SURFACE*  
*FT\_FEATURE\_ERROR\_TOO\_LARGE*  
*FT\_DEGENERATE\_PATCH\_CREATED*  
*FT\_SURFACE\_ALREADY\_CREATED*

*FT\_COULD\_NOT\_SMOOTH\_SURFACESET*  
*FT\_NO\_SMOOTHING*  
*FT\_FAILED\_CREATING\_GRAPH*  
*FT\_GRID\_NOT\_CREATED*  
*FT\_SURFACE\_NOT\_MODIFIED*

Definition at line 51 of file ftMessage.h.

## 28.1.3.13 enum Go::ftTangPriority

Whether the group of objects (surfaces) are a master, a slave or not specified. Related to tangent plane continuity between groups of surfaces

Enumerator

*ftNoType*  
*ftMaster*  
*ftSlave*

Definition at line 49 of file ftTangPriority.h.

## 28.1.3.14 enum Go::IGESSection

Enumerator

**S**  
**G**  
**D**  
**P**  
**T**  
**E**

Definition at line 75 of file IGESconverter.h.

## 28.1.3.15 enum Go::IntersectionType

Enumerator

**No\_Type**  
**SurfaceModel\_SurfaceModel**  
**SurfaceModel\_Plane**  
**SurfaceModel\_Line**  
**CompositeCurve\_CompositeCurve**  
**CompositeCurve\_Plane**  
**CompositeCurve\_Line**

Definition at line 54 of file IntResultsModel.h.

## 28.1.3.16 enum Go::IntPtClassification

Enumeration used to classify the direction of an intersection curve passing through an intersection point with respect to surface boundaries

Enumerator

**DIR\_UNDEF** Not defined.  
**DIR\_IN** Tangent of the intersection curve pointing into the domain.  
**DIR\_OUT** Tangent of the intersection curve pointing out from the domain.  
**DIR\_PARALLEL** Tangent of the intersection curve parallel to the domain.  
**DIR\_PERPENDICULAR** Tangent of the intersection curve perpendicular to the domain.  
**DIR\_HIGHLY\_SINGULAR** No defined tangent.  
**DIR\_TOUCH** Tangent touching the domain at a corner.

Definition at line 54 of file IntersectionPointUtils.h.

## 28.1.3.17 enum Go::IntPtLocation

Enumeration used to classify the location of an intersection point in the parameter domain of the object.

Enumerator

**LOC\_OUTSIDE\_BOTH** [Point](#) is outside domain for both objects.  
**LOC\_INSIDE\_BOTH** [Point](#) is inside domains (inner point) for both objects.  
**LOC\_EDGE\_ONE** [Point](#) is on the edge of at least one object.  
**LOC\_CORNER\_ONE** [Point](#) is on the corner of at least one object.  
**LOC\_CORNER\_BOTH** [Point](#) is on the corner of both objects.  
**LOC\_EDGE\_BOTH** [Point](#) is on the edge of both objects.

Definition at line 77 of file IntersectionPointUtils.h.

## 28.1.3.18 enum Go::IteratorType

Enumerator

**Iterator\_parametric**  
**Iterator\_geometric**

Definition at line 54 of file ParamSurface.h.

## 28.1.3.19 enum Go::LinkType

A classification of [IntersectionLink](#) objects. The classification is strictly based on how it was made within the algorithm.

Enumerator

**LINK\_UNDEFINED** 0  
**SIMPLE\_CONE** 1  
**SIMPLE\_MONOTONE** 2  
**SIMPLE\_IMPLICIT** 3  
**SIMPLE\_TWO\_POINTS** 4  
**COINCIDENCE\_CVPT** 5  
**COINCIDENCE\_CVCV** 6  
**COINCIDENCE\_SFCV** 7  
**COINCIDENCE\_SFPT** 8  
**MICRO\_CVCV** 9  
**MICRO\_SFPT** 10  
**MICRO\_SFCV** 11  
**MICRO\_SFSF** 12  
**MICRO\_PAR1FUNC** 13  
**MICRO\_PAR2FUNC** 14  
**LINEAR\_CVCV** 15

**LINEAR\_SFCV** 16  
**LINEAR\_SFSF** 17  
**MERGED\_UNDEFINED** 18  
**MERGED\_SIMPLE\_CONE** 19  
**MERGED\_SIMPLE\_MONOTONE** 20  
**MERGED\_SIMPLE\_CONE\_MONOTONE** 21  
**MERGED\_COINCIDENCE\_SFCV\_SFCV** 22  
**DEG\_TRIANGLE** 23  
**POST\_ITERATE** 24  
**BRANCH\_CONNECTION** 25  
**COMPLEX\_SFSF** 26  
**SPLIT\_LINK** 27  
**REPAIRED\_MISSING\_LINK** 28  
**INSIDE\_OUTSIDE\_SINGULARITY\_BOX** 29

Definition at line 50 of file LinkType.h.

#### 28.1.3.20 enum Go::PointSequenceType

Type of point.

Enumerator

**PSTPoint** Each grid position holds a point.  
**PSTPointTangent** Each grid position holds a point, then a tangent.  
**PSTScattered** Regard this an unordered point cloud.

Definition at line 53 of file PointSequence.h.

#### 28.1.3.21 enum Go::RegistrationReturnType

Enumerator for registration error reasons  
**RegistrationOK** No error found  
**TooFewPoints** Less than three points are given  
**PointSetSizeDiff** The two point sets given have different length  
**AreaTooSmall** Failed to find a tripple of points that are far enough from being almost colinear  
**SolveFailed** Solving the linear system in the Newtons approach method failed. Error code is stored in registrationData.solve\_code

Enumerator

**RegistrationOK**  
**TooFewPoints**  
**PointSetSizeDiff**  
**AreaTooSmall**  
**SolveFailed**

Definition at line 57 of file RegistrationUtils.h.

### 28.1.3.22 enum Go::SingularityClassification

This enum classifies the type of singularity.

Enumerator

***NO\_SING***  
***INIT\_SING***  
***DIVIDED\_SING***  
***KEEP\_SING***

Definition at line 49 of file SingularityClassification.h.

### 28.1.3.23 enum Go::SingularityType

A classification of an [IntersectionPoint](#), based on the nature of the intersection on which it lies.

Enumerator

***ORDINARY\_POINT*** [IntersectionPoint](#) lies on normal, transversal intersection.  
***TANGENTIAL\_POINT*** The two intersecting objects are tangent to each other at the location of this [IntersectionPoint](#).  
***ISOLATED\_POINT*** This is an isolated [IntersectionPoint](#) (does not lie on an [IntersectionCurve](#) or on a partial coincidence area).  
***BRANCH\_POINT*** This is an [IntersectionPoint](#) where flere interection curves meet.  
***HIGHER\_ORDER\_POINT*** The two objects intersecting at this point have same tangent plane AND curvature.

Definition at line 46 of file SingularityType.h.

### 28.1.3.24 enum Go::SubdivisionClassification

This enum classifies the type of subdivision.

Enumerator

***CANNOT\_SUBDIVIDE***  
***DIVIDE\_DEG***  
***DIVIDE\_CRITICAL***  
***DIVIDE\_HIGH\_SING***  
***DIVIDE\_SING***  
***DIVIDE\_KNOT***  
***DIVIDE\_INT***  
***DIVIDE\_PAR***

Definition at line 49 of file SubdivisionClassification.h.

## 28.1.3.25 enum Go::TangentDomain

Enumerator

***GEOM***  
***PARAM1***  
***PARAM2***

Definition at line 56 of file IntersectionCurve.h.

## 28.1.3.26 enum Go::testSuite

Enumerator

***IDENTICAL\_VERTICES***  
***IDENTICAL\_EDGES***  
***EMBEDDED\_EDGES***  
***IDENTICAL\_FACES***  
***EMBEDDED\_FACES***  
***MINI\_CURVE***  
***MINI\_SURFACE***  
***MINI\_EDGE***  
***MINI\_FACE***  
***SLIVER\_FACE***  
***NARROW\_REGION***  
***DEGEN\_SRF\_BD***  
***DEGEN\_SRF\_CORNER***  
***VANISHING\_TANGENT***  
***VANISHING\_NORMAL***  
***EDGE\_VERTEX\_DISTANCE***  
***FACE\_VERTEX\_DISTANCE***  
***FACE\_EDGE\_DISTANCE***  
***EDGE\_POSITION\_DISCONT***  
***EDGE\_TANGENTIAL\_DISCONT***  
***FACE\_POSITION\_DISCONT***  
***FACE\_TANGENTIAL\_DISCONT***  
***LOOP\_CONSISTENCY***  
***LOOP\_ORIENTATION***  
***FACE\_ORIENTATION***  
***CV\_G1DISCONT***  
***CV\_C1DISCONT***  
***SF\_G1DISCONT***  
***SF\_C1DISCONT***  
***CV\_CURVATURE\_RADIUS***  
***SF\_CURVATURE\_RADIUS***  
***EDGE\_ACUTE\_ANGLE***  
***FACE\_ACUTE\_ANGLE***  
***LOOP\_INTERSECTION***  
***LOOP\_SELF\_INTERSECTION***  
***INDISTINCT\_KNOTS***

Definition at line 51 of file testSuite.h.

## 28.1.3.27 enum Go::tpJointType

Enumerator

**JOINT\_G1**  $G^1$  continuous (angle diff. less than kink tolerance) Continuous (angle diff. between kink and bend tolerance)  
**JOINT\_KINK** Continuous (angle diff. greater than bend tolerance)  
**JOINT\_G0** Discontinuous (distance between gap and neighbour tol.)  
**JOINT\_GAP** Discontinuous (distance greater than neighbour tolerance)  
**JOINT\_DISC** No joint, this was the last segment.  
**JOINT\_NONE**

Definition at line 46 of file tpJointType.h.

## 28.1.4 Function Documentation

28.1.4.1 void Go::add\_reachables\_from ( const IntersectionPoint \* *pt*, const IntersectionPoint \* *last\_pt*, std::set< IntersectionPoint \* > & *result* )

Definition at line 426 of file IntersectionPoolUtils.h.

28.1.4.2 void Go::addToLinearSystem ( int *pt\_idx*, const std::vector< Point > & *points\_fixed*, const std::vector< Point > & *points\_transform*, bool *allow\_rescaling*, const std::vector< std::vector< double > > & *id*, const Point & *fine\_R*, const Point & *fine\_T*, double *fine\_s*, const std::vector< std::vector< double > > & *m\_rot\_R*, double *s2*, double *R2*, bool *zero\_R*, const std::vector< std::vector< std::vector< double > > > & *lhs\_matrix*, const std::vector< std::vector< double > > & *rhs\_matrix* )

Add the contribution from one single point to the linear system coefficients used during fine registration.

28.1.4.3 template<typename T> T Go::area ( const Array< T, 2 > \* *c* ) [inline]

Computes the area of a 2-dimensional triangle. Input is an array of corner points. Same function also exists for 3-dimensional triangles.

Definition at line 91 of file Volumes.h.

28.1.4.4 template<typename T> T Go::area ( const Array< T, 3 > \* *c* ) [inline]

Computes the area of a 2-dimensional triangle. Input is an array of corner points. Same function also exists for 2-dimensional triangles.

Definition at line 98 of file Volumes.h.

28.1.4.5 double Go::areaTriangle ( const Vector2D & *corner1*, const Vector2D & *corner2*, const Vector2D & *corner3* )

28.1.4.6 template<typename SquareMatrix, typename T> void Go::backwardSubstitution ( const SquareMatrix & *U*, T \* *x*, int *num\_unknowns* )

Using backward substitution to calculate  $x$  on the system  $Ux = b$ , where  $U$  is an upper triangular matrix with unitary diagonal.

## Parameters

|                     |                                                                                                                                                                                          |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>U</i>            | The upper triangular matrix. The actually used class must support the operation <code>[][]</code> and return 'double'.                                                                   |
| <i>x</i>            | At function invocation, <i>x</i> should point to an array of T, containing the vector 'b'. On successful completion of the function, this array will contain the solution for <i>x</i> . |
| <i>num_unknowns</i> | The system size (number of unknowns).                                                                                                                                                    |

Definition at line 178 of file LUDecomp\_implementation.h.

```
28.1.4.7 template<typename SquareMatrix > void Go::backwardSubstitution (const SquareMatrix & U, std::vector<
double > * x, int num_unknowns)
```

Using backward substitution to calculate *x* on the system  $Ux = b$ , where *U* is an upper triangular matrix with unitary diagonal.

## Parameters

|                     |                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>U</i>            | The upper triangular matrix. The actually used class must support the operation <code>[][]</code> and return 'double'.                                                                          |
| <i>x</i>            | At function invocation, <i>x</i> should point to a vector of doubles, containing the vector 'b'. On successful completion of the function, this vector will contain the solution for <i>x</i> . |
| <i>num_unknowns</i> | The system size (number of unknowns).                                                                                                                                                           |

Definition at line 192 of file LUDecomp\_implementation.h.

```
28.1.4.8 double Go::benchmarkSfRefinement (LRSplineSurface & lr_sf, const std::vector<
LRSplineSurface::Refinement2D > & refs, bool single_insertions = false)
```

```
28.1.4.9 template<int Ndim> void Go::bernsteinToSpline (const Array< BernsteinPoly, Ndim > & curve_bp, bool
rational, SplineCurve & segment)
```

Converts an [Array](#) of *Ndim* BernsteinPolys to a [SplineCurve](#) segment. If the wanted [SplineCurve](#) is rational, *Ndim* is equal to  $dim+1$ , where *dim* is the dimension of space. Furthermore, in *curve\_bp*, the weights are included in the space part of the coefficients, i.e. they have the form  $wP1, wP2, \dots, wPdim, w$ .

## Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>curve_bp</i> | an <a href="#">Array</a> of <i>Ndim</i> BernsteinPolys |
| <i>rational</i> | flag to indicate if the objects are rational           |
| <i>segment</i>  | the resulting spline curve segment                     |

Definition at line 184 of file BernsteinUtils.h.

```
28.1.4.10 template<int Ndim> void Go::bernsteinToSpline (const Array< BernsteinMulti, Ndim > & surface_bm, bool
rational, SplineSurface & patch)
```

Converts an [Array](#) of *Ndim* BernsteinMultis to a [SplineSurface](#) patch. If the wanted [SplineSurface](#) is rational, *Ndim* is equal to  $dim+1$ , where *dim* is the dimension of space. Furthermore, in *surface\_bm*, the weights are included in

the space part of the coefficients, i.e. they have the form  $wP_1, wP_2, \dots, wP_{dim}, w$ .

#### Parameters

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <i>surface_bm</i> | an <a href="#">Array</a> of <i>Ndim</i> BernsteinMultis |
| <i>rational</i>   | flag to indicate if the objects are rational            |
| <i>patch</i>      | the resulting spline surface patch                      |

Definition at line 220 of file BernsteinUtils.h.

28.1.4.11 `double Go::binom ( int n, int i ) [inline]`

Computes the binomial coefficient:  $n! / (i! (n-i)!)$

Definition at line 50 of file binom.h.

28.1.4.12 `template<class Functor > double Go::brent_minimize ( const Functor & f, double a, double b, double c, double & parmin, const double rel_tolerance = std::sqrt (std::numeric_limits<double>::epsilon()) ) [inline]`

Definition at line 78 of file brent\_minimize.h.

28.1.4.13 `void Go::cart_to_bary ( const SplineCurve & cv, const BaryCoordSystem2D & bc, SplineCurve & cv_bc )`

Creates a new curve with control points in 3 barycentric coordinates from the 2D input curve.

28.1.4.14 `void Go::cart_to_bary ( const SplineCurve & cv, const BaryCoordSystem3D & bc, SplineCurve & cv_bc )`

Creates a new curve with control points in 4 barycentric coordinates from the 3D input curve.

28.1.4.15 `void Go::cart_to_bary ( const SplineSurface & sf, const BaryCoordSystem3D & bc, SplineSurface & sf_bc )`

Creates a new surface with control points in 4 barycentric coordinates from the 3D input surface.

28.1.4.16 `void Go::cart_to_bary ( const PointCloud3D & cloud, const BaryCoordSystem3D & bc, PointCloud4D & cloud_bc )`

Creates a new point cloud in 4 barycentric coordinates from the 3D input cloud.

28.1.4.17 `int Go::checkCoincide ( ParamCurveInt * curve, double start, double end, shared_ptr< GeoTol > tol, ParamCurveInt * other, double other_start, double other_end )`

Check if two curves are coinciding between parameters start and end on this curve, and other\_start and other\_end on the other curve.

28.1.4.18 `int Go::checkCoincide ( ParamCurveInt * curve, double start, double end, ParamSurfaceInt * surf, Point su_start, Point su_end, shared_ptr< GeoTol > tol )`

Check if this curve is coinciding between parameters start and end, with the [ParamSurface](#) between parameters su\_start and su\_end.

28.1.4.19 `int Go::checkCoincide ( ParamCurveInt * curve, double start, double end, SplineSurfaceInt * surf, const Point & su_start, const Point & su_end, shared_ptr< GeoTol > tol )`

Check if this curve is coinciding between parameters start and end, with the [SplineSurface](#) between parameters su\_start and su\_end.

28.1.4.20 `int Go::checkCoincide ( Param1FunctionInt * func1, double start, double end, Param0FunctionInt * C, shared_ptr< GeoTol > tol )`

Check if this function is coinciding between parameters start and end, with the [Point](#).

28.1.4.21 `int Go::checkCoincide ( ParamSurfaceInt * surf1, ParamSurfaceInt * surf2, std::vector< double > & par_loop, const shared_ptr< GeoTol > tol )`

by the parameter values of the intersection points representing it

Check if the two given surfaces coincide within the loop given

28.1.4.22 `std::vector<float> Go::closestDistances ( const std::vector< float > & pts, const shared_ptr< boxStructuring::BoundingBoxStructure > & structure, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation )`

Calculates the distance for each point in a point cloud to a given surface model, after a SO(3)-rotation and translation is applied on the point cloud. pts - The point cloud, of length 3N where N is the number of points, on format p[0][0], p[0][1], p[0][2], p[1][0], ... structure - the preprocessed structure used to improve the calculation speed. This also holds the surface model. rotationMatrix - An orthogonal 3x3 matrix describing the rotation to be applied in the point cloud before starting the calculations translation - A translation vector to be added to the point cloud (after the orthogonal rotation) before starting the calculations returns a vector of length pts.size()/3, holding the distances in the same order as the input points

28.1.4.23 `std::vector<float> Go::closestPointCalculations ( const std::vector< float > & pts, const shared_ptr< boxStructuring::BoundingBoxStructure > & structure, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation, int return_type, int start_idx, int skip, int max_idx, int search_extend = 3, bool m_core = true )`

Calculates the closest points of a point cloud to a surface model, after a SO(3)-rotation and translation is applied on the point cloud. The method uses polygons inside the bounding curves on parameter domains to help determining if parameter pairs are inside the parameter domain. NB! The creation of the polygons is not yet proven to guarantee inside polygons, thus there is a theoretical risk of not getting the closest point in every case. pts - The point cloud, of length 3N where N is the number of points, on format p[0][0], p[0][1], p[0][2], p[1][0], ... structure - the preprocessed structure used to improve the calculation speed. This also holds the surface model. rotationMatrix - An orthogonal 3x3 matrix describing the rotation to be applied in the point cloud before starting the calculations translation - A translation vector to be added to the point cloud (after the orthogonal rotation) before starting the calculations

return\_type - Tell whether the distances (0), signed distances (1) or closest points (2) should be returned start\_idx - Used for defining the subset of the points on which the calculation should be performed, see below skip - Used for defining the subset of the points on which the calculation should be performed, see below max\_idx - Used for defining the subset of the points on which the calculation should be performed. The subset consists of the points with index  $idx = skip + N * step$  such that  $start\_idx \leq idx < max\_idx$ . For calculations on the entire point cloud, use  $start\_idx = 0$ ,  $skip = 1$  and  $max\_idx \geq$  number of points search\_extend - Used to define the number of segments to be added in each direction when defining the parameter subset on which the closest point functions should be performed. Will be removed. m\_core - Whether the calculations should be performed in parallel on multiple cores (only if OPENMP is included) returns A vector of the distances to the closest points for the subset on which the calculations are performed.

28.1.4.24 `std::vector<float> Go::closestPointCalculations ( const std::vector< float > & pts, const shared_ptr< boxStructuring::BoundingBoxStructure > & structure, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation, int return_type )`

Make closest point calculations on the entire set of a point cloud. For return\_type == 0, the distances are returned For return\_type == 1, the signed distances are returned For return\_type == 2, the points are returned

28.1.4.25 `std::vector<float> Go::closestPoints ( const std::vector< float > & pts, const shared_ptr< boxStructuring::BoundingBoxStructure > & structure, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation )`

Calculates the closest point for each point in a point cloud to a given surface model, after a SO(3)-rotation and translation is applied on the point cloud. pts - The point cloud, of length 3N where N is the number of points, on format  $p[0][0]$ ,  $p[0][1]$ ,  $p[0][2]$ ,  $p[1][0]$ , ... structure - the preprocessed structure used to improve the calculation speed. This also holds the surface model. rotationMatrix - An orthogonal 3x3 matrix describing the rotation to be applied in the point cloud before starting the calculations translation - A translation vector to be added to the point cloud (after the orthogonal rotation) before starting the calculations returns a vector of same length as pts, holding the closest point coordinates in the same order as the input points

28.1.4.26 `void Go::closestPointSingleCalculation ( int pt_idx, int start_idx, int skip, const std::vector< float > & inPoints, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation, const shared_ptr< boxStructuring::BoundingBoxStructure > & boxStructure, std::vector< float > & result, std::vector< std::vector< int > > & lastBoxCall, int return_type, int search_extend )`

28.1.4.27 `void Go::closestPtCurves ( SplineCurve * cv1, SplineCurve * cv2, double epsge, double & par1, double & par2, double & dist )`

Compute the closest point between two curves

#### Parameters

|              |                             |
|--------------|-----------------------------|
| <i>cv1</i>   | pointer to the first curve  |
| <i>cv2</i>   | pointer to the second curve |
| <i>epsge</i> | geometrical tolerance       |

#### Return values

|             |                                                    |
|-------------|----------------------------------------------------|
| <i>par1</i> | parameter of the closest point in the first curve  |
| <i>par2</i> | parameter of the closest point in the second curve |

## Return values

|             |                                                  |
|-------------|--------------------------------------------------|
| <i>dist</i> | distance between the curves at the closest point |
|-------------|--------------------------------------------------|

28.1.4.28 `std::vector<float> Go::closestSignedDistances ( const std::vector< float > & pts, const shared_ptr< boxStructuring::BoundingBoxStructure > & structure, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation )`

Calculates the signed distance for each point in a point cloud to a given surface model, after a SO(3)-rotation and translation is applied on the point cloud. For every point the signed distance

- has absolute value equal to the distance between the point and the closest point on the surface model
- is positive if the point is outside the model
- is negative if the point is inside the model  
 pts - The point cloud, of length 3N where N is the number of points, on format p[0][0], p[0][1], p[0][2], p[1][0], ...  
 structure - the preprocessed structure used to improve the calculation speed. This also holds the surface model.  
 rotationMatrix - An orthogonal 3x3 matrix describing the rotation to be applied in the point cloud before starting the calculations  
 translation - A translation vector to be added to the point cloud (after the orthogonal rotation) before starting the calculations  
 returns a vector of length pts.size()/3, holding the signed distances in the same order as the input points

28.1.4.29 `std::vector<float> Go::closestVectorsOld ( const std::vector< float > & inPoints, const shared_ptr< boxStructuring::BoundingBoxStructure > & boxStructure, const std::vector< std::vector< double > > & rotationMatrix, const Point & translation, int return_type, int start_idx, int skip, int max_idx, int search_extend = 3 )`

Calculates the closest points of a point cloud to a surface model, by not using the inside polygons in closestVectors()

28.1.4.30 `template<class T1, class T2> bool Go::compare_first ( const std::pair< T1, T2 > & x, const std::pair< T1, T2 > & y )`

Definition at line 254 of file IntersectionPoolUtils.h.

28.1.4.31 `template<typename Iterator > int Go::compare_seq ( Iterator begin_1, Iterator end_1, Iterator begin_2, Iterator end_2 )`

Definition at line 161 of file checks.h.

28.1.4.32 `template<class PtrToCurveType > double Go::computeLoopGap ( const std::vector< PtrToCurveType > & curves ) [inline]`

Computes the largest gap in the loop specified by the vector of curves.

Definition at line 55 of file CurveLoop.h.

28.1.4.33 `template<class iterator > shared_ptr<IntersectionCurve> Go::constructIntersectionCurve ( const iterator begin, const iterator end )`

Definition at line 601 of file IntersectionCurve.h.

28.1.4.34 `void Go::create_bary_coord_system2D ( const SplineCurve & curve, BaryCoordSystem2D & bc )`

Creates a barycentric coordinate system from a given spline curve.

28.1.4.35 `void Go::create_bary_coord_system3D ( const SplineCurve & curve, BaryCoordSystem3D & bc )`

Creates a barycentric coordinate system from a given 3D spline curve.

28.1.4.36 `void Go::create_bary_coord_system3D ( const SplineSurface & surface, BaryCoordSystem3D & bc )`

Creates a barycentric coordinate system from a given spline surface.

28.1.4.37 `void Go::create_bary_coord_system3D ( const PointCloud3D & cloud, BaryCoordSystem3D & bc )`

Creates a barycentric coordinate system from a point cloud.

28.1.4.38 `void Go::create_bary_coord_system3D ( const BoundingBox & box, BaryCoordSystem3D & bc )`

Creates a barycentric coordinate system from a bounding box.

28.1.4.39 `double Go::curvatureRadius ( const std::vector< Point > & der, std::vector< Point > & unitder )`

Help functions in related to curvature. Given position, first and second derivative of a curve passing through a point, compute the unit tangent, curvature vector and curvature radius of this curve.

28.1.4.40 `SISLCurve GO_API* Go::Curve2SISL ( const SplineCurve & cv, bool copy = true )`

Convert a [SplineCurve](#) to a [SISLCurve](#)

#### Parameters

|             |                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cv</i>   | the <a href="#">SplineCurve</a> to convert                                                                                                                                                                                                                              |
| <i>copy</i> | if 'true', then the generated <a href="#">SISLCurve</a> will have its own copy of the coefficient information contained in 'cv'. Otherwise, it will share this information with 'cv' (ie. it will only contain a pointer into the corresponding storage array in 'cv'). |

**Returns**

A newly generated [SISLCurve](#) that describes the same curve as 'cv'. The user assumes ownership and is responsible for cleaning up (which means calling the SISL function `freeCurve(...)` on the pointer when it should be destroyed).

**28.1.4.41** `SISLCurve GO_API* Go::Curve2SISL_rat ( const SplineCurve & cv )`

Convert a [SplineCurve](#) to a rational [SISLCurve](#) Arrays are copied

**28.1.4.42** `void Go::debug_write_line ( const Point & p1, const Point & p2, const char * fname )`

Definition at line 70 of file `IntersectionPoolUtils.h`.

**28.1.4.43** `void Go::debug_write_point ( const Point & p1, const char * fname )`

Definition at line 86 of file `IntersectionPoolUtils.h`.

**28.1.4.44** `bool Go::degenerate_triangle ( const Vector2D & c1, const Vector2D & c2, const Vector2D & c3 )`

**28.1.4.45** `template<typename T> T Go::determinantOf ( const Array< T, 2 > * a ) [inline]`

Calculates the determinant of a 2 x 2 matrix, represented in memory as a sequence of 2 [Array](#) s of length 2. Same function also exists for 3 x 3 matrices.

Definition at line 55 of file `Volumes.h`.

**28.1.4.46** `template<typename T> T Go::determinantOf ( const Array< T, 3 > * a ) [inline]`

Calculates the determinant of a 3 x 3 matrix, represented in memory as a sequence of 3 [Array](#) s of length 3. Same function also exists for 2 x 2 matrices.

Definition at line 65 of file `Volumes.h`.

**28.1.4.47** `void Go::determine_seed ( double * par, int par_start, int par_end, const Point & pt, const IntersectionPoint *const ip1, const IntersectionPoint *const ip2 )`

Definition at line 468 of file `IntersectionPoolUtils.h`.

- 28.1.4.48 `bool Go::determineCoincidenceRegion ( const ParamObjectInt * obj1, const ParamObjectInt * obj2, shared_ptr< const GeoTol > tol, const double * current_params, int dir, bool forward, double & last_param_val_inside, double & first_param_val_outside )`
- 28.1.4.49 `bool Go::determineCoincidenceRegion ( const ParamFunctionInt * obj_1d, double C, shared_ptr< const GeoTol > tol, const double * current_params, int dir, bool forward, double & last_param_val_inside, double & first_param_val_outside )`
- 28.1.4.50 `void Go::estimate_seed_by_interpolation ( const IntersectionPoint * p1, const IntersectionPoint * p2, int fixed_dir, double fixed_value, double * result )`

Definition at line 444 of file IntersectionPoolUtils.h.

- 28.1.4.51 `void Go::evalDistCurve ( const std::vector< Point > & marching_curve, const std::vector< Point > & other_curve, std::vector< Point > & dist_curve )`
- 28.1.4.52 `int Go::evalProjectedCurve ( const std::vector< Point > & ft, const std::vector< Point > & gs, std::vector< Point > & res )`
- 28.1.4.53 `void Go::extract_chains ( const std::vector< shared_ptr< IntersectionPoint > > pts, std::vector< std::vector< shared_ptr< IntersectionPoint > > > & chains )`

Definition at line 537 of file IntersectionPoolUtils.h.

- 28.1.4.54 `int Go::extremalPtSurfSurf ( ParamSurface * psurf1, ParamSurface * psurf2, int constraints[2], double constraints_par[2], double limit[,], double enext[,], double gpos[,], double angle_tol )`

Finds one point in each surface where the two normals are parallel to each other and to the difference vector between the two points. The edge info makes it possible to constrain the search to an ISO-curve in one of or both surfaces. Ported from the sisl-function `shsing_ext`.

METHOD : - Start with a guess value (u,v) in domain of surface 1 (S(u,v))  
 (a) - Find domain value (r,t) of closest point (to S(u,v) in surface 2 (Q(r,t))  
 - If  $vf1(u,v) = \langle Su, Normal(Q) \rangle$  and  $vf2(u,v) = \langle Sv, Normal(Q) \rangle$  is small enough stop  
 ( $\langle, \rangle$  means scalar prod.)  
 - Find du and dv by taylorizing vf1 and vf2.  
 This include finding the derivatives of the closest point function (r(u,v),t(u,v)) with respect to u and v. (called h(u,v) in article, see comments in `shsing_s9dir`)  
 -  $u := u + du$   $v := v + dv$ , goto (a)

| <i>enext</i>           | Parameter start value for iteration(4 values).                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>angle_tol</i>       | The angular tolerance for success.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>gpos</i>            | Parameter values of the found singularity(4 values).                                                                                                                                                                                                                                                                                                                                                                                      |

#### Returns

Status message. =1 Extremum found. = 0 Extremum NOT found.

**28.1.4.55** `double Go::factorial ( int n ) [inline]`

computes  $n!$  (n factorial)

Definition at line 82 of file `binom.h`.

**28.1.4.56** `int Go::find_point_in ( IntersectionPoint * p, const std::vector< shared_ptr< IntersectionPoint > > & vec )`

Definition at line 491 of file `IntersectionPoolUtils.h`.

**28.1.4.57** `RegistrationResult Go::fineRegistration ( const std::vector< Point > & points_fixed, const std::vector< Point > & points_transform, bool allow_rescaling, RegistrationInput params )`

Given two sequences of points in 3D, get the rotation, rescaling (optional) and translation that sends the second point set as close as possible to the first (i.e. that minimizes the sum of the square distances). The sequences must be of same length (at least three), and the points will be matched in the order they come in the vectors, i.e. `points_transform[i]` should, after the transformation, be close to `points_fixed[i]`. The method works best if the point sets already are close to each other, but not necessarily in optimal position.

28.1.4.58 `Direction2D Go::flip ( Direction2D d ) [inline]`

Definition at line 430 of file Mesh2D.h.

28.1.4.59 `IntersectionPoint* Go::flip_intersecting_objects ( IntersectionPoint * p )`

Definition at line 106 of file IntersectionPoolUtils.h.

28.1.4.60 `template<typename SquareMatrix , typename T > void Go::forwardSubstitution ( const SquareMatrix & L, T * x, int num_unknowns )`

Using forward substitution to calculate  $x$  on the system  $Lx = b$ , where  $L$  is a lower triangular matrix with unitary diagonal.

#### Parameters

|                 |                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $L$             | The lower triangular matrix. The actually used class must support the operation <code>[][]</code> and return 'double'.                                                            |
| $x$             | At function invocation, $x$ should point to an array of $T$ , containing the vector 'b'. On successful completion of the function, this array will contain the solution for $x$ . |
| $num\_unknowns$ | The system size (number of unknowns).                                                                                                                                             |

Definition at line 151 of file LUDecomp\_implementation.h.

28.1.4.61 `template<typename SquareMatrix > void Go::forwardSubstitution ( const SquareMatrix & L, std::vector< double > * x, int num_unknowns )`

Using forward substitution to calculate  $x$  on the system  $Lx = b$ , where  $L$  is a lower triangular matrix with unitary diagonal.

#### Parameters

|                 |                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $L$             | The lower triangular matrix. The actually used class must support the operation <code>[][]</code> and return 'double'.                                                                |
| $x$             | At function invocation, $x$ should point to a vector of doubles, containing the vector 'b'. On successful completion of the function, this vector will contain the solution for $x$ . |
| $num\_unknowns$ | The system size (number of unknowns).                                                                                                                                                 |

Definition at line 163 of file LUDecomp\_implementation.h.

28.1.4.62 `template<typename Functor > double Go::gaussian_quadrature ( Functor & f, double a, double b )`

Routine to calculate the integral of the functor  $f$  from  $a$  to  $b$  using Gaussian quadrature with  $W=1$  and  $N=10$ .

Definition at line 110 of file Integration.h.

28.1.4.63 `template<typename Functor2D > double Go::gaussian_quadrature2D ( Functor2D & f, double ax, double bx, double ay, double by )`

Routine to integrate the two-dimensional functor *f* over the rectangle defined by *ax*, *bx*, *ay* and *by*. Uses Gaussian quadrature.

Definition at line 173 of file *Integration.h*.

28.1.4.64 `void Go::GaussQuadInner ( const BsplineBasis & basis, int ider, double lim1, double lim2, double *** integral )`

Compute all definite integrals of inner products of derivatives of B-splines up to a given order where the differentiation is of the same order for both B-splines. The interval of integration are equal to the parameter intervals of the surface in the current par. dir.

#### Parameters

|                 |                                   |
|-----------------|-----------------------------------|
| <i>basis</i>    | B-spline basis.                   |
| <i>ider</i>     | Number of derivatives to compute. |
| <i>lim1</i>     | Start of parameter interval.      |
| <i>lim2</i>     | End of parameter interval.        |
| <i>integral</i> | Computed integrals.               |

28.1.4.65 `void Go::GaussQuadInner2 ( const BsplineBasis & basis, int ider, double lim1, double lim2, double ** integral )`

Compute all definite integrals of inner products of derivatives of B-splines up to a given order where the differentiation is of the same order for both B-splines. The interval of integration are equal to the parameter intervals of the surface in the current par. dir.

#### Parameters

|                 |                                   |
|-----------------|-----------------------------------|
| <i>basis</i>    | B-spline basis.                   |
| <i>ider</i>     | Number of derivatives to compute. |
| <i>lim1</i>     | Start of parameter interval.      |
| <i>lim2</i>     | End of parameter interval.        |
| <i>integral</i> | Computed integrals.               |

28.1.4.66 `void Go::GaussQuadInnerFlat ( const BsplineBasis & basis, int derivs, int start_der, int gap, double lim1, double lim2, std::vector< double > & integral )`

Compute all definite integrals of inner products of derivatives of B-splines up to a given order where the gap between the order of differentiation on the first and second B-spline is constant. The interval of integration are equal to the parameter intervals of the surface in the current par. dir.

#### Parameters

|              |                 |
|--------------|-----------------|
| <i>basis</i> | B-spline basis. |
|--------------|-----------------|

## Parameters

|                  |                                      |
|------------------|--------------------------------------|
| <i>derivs</i>    | Number of derivatives to compute.    |
| <i>gap</i>       | Difference between derivation order. |
| <i>start_der</i> | First derivative to compute.         |
| <i>lim1</i>      | Start of parameter interval.         |
| <i>lim2</i>      | End of parameter interval.           |
| <i>integral</i>  | Computed integrals.                  |

28.1.4.67 `void Go::GaussQuadInnerRational ( const BsplineBasis & basis, int ider, double lim1, double lim2, shared_ptr< SplineCurve > bspline_curve, double *** integral )`

Compute all definite integrals of inner products of derivatives of rational B-splines up to a given order where the differentiation is of the same order for both B-splines. The interval of integration are equal to the parameter intervals of the surface in the current par. dir.

## Parameters

|                      |                                            |
|----------------------|--------------------------------------------|
| <i>basis</i>         | B-spline basis.                            |
| <i>ider</i>          | Number of derivatives to compute.          |
| <i>lim1</i>          | Start of parameter interval.               |
| <i>lim2</i>          | End of parameter interval.                 |
| <i>bspline_curve</i> | 1-dim rational 0-function defining weights |
| <i>coefs</i>         | Wiegths for denominator function           |
| <i>integral</i>      | Computed integrals.                        |

28.1.4.68 `void Go::GaussQuadValues ( const BsplineBasis & basis, std::vector< double > & parameters, std::vector< double > & par_weights )`

Functions used to compute integrals of inner products of B-splines.

Store parameters and weights used for numerical integration by Gauss quadrature. All parameter values for all Bezier segments are stored in parameters, while the weights within an interval is stored only once in weights. Thus, the lenght of weights gives the number of samples for each Bezier segment.

## Parameters

|                    |                                 |
|--------------------|---------------------------------|
| <i>basis</i>       | B-spline basis                  |
| <i>parameters</i>  | Parameter values for all points |
| <i>par_weights</i> | Weight for each parameter       |

28.1.4.69 `double Go::getCurrentTime ( )`

Number of seconds since some (probably system-dependent) epoch.

28.1.4.70 `void Go::getHermiteData ( const std::vector< Point > & der1, const std::vector< Point > & der2, double & parint, double & len1, double & len2 )`

Given position, first and second derivative in both ends of an Hermite segment, compute parameter interval and tangent lengths in order to stay close to a circular segment.

28.1.4.71 `SISLSurf GO_API* Go::GoSurf2SISL ( const SplineSurface & sf, bool copy = true )`

Convert a [SplineSurface](#) to a SISLSurface

#### Parameters

|             |                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sf</i>   | the <a href="#">SplineSurface</a> to convert                                                                                                                                                                                                                           |
| <i>copy</i> | if 'true', then the generated <a href="#">SISLSurf</a> will have its own copy of the coefficient information contained in 'sf'. Otherwise, it will share this information with 'sf' (ie. it will only contain a pointer into the corresponding storage array in 'sf'). |

#### Returns

a newly generated [SISLSurf](#) that describes the same surface as 'sf'. The user assumes ownership and is responsible for cleaning up (which means calling the SISL function `freeSurf(...)` on the pointer when it should be destroyed).

28.1.4.72 `void Go::intersect2Dcurves ( const ParamCurve * cv1, const ParamCurve * cv2, double epsge, std::vector< std::pair< double, double > > & intersections, std::vector< int > & pretopology, std::vector< std::pair< std::pair< double, double >, std::pair< double, double > > > & int_crvs )`

Intersect two 2D spline curves. Collect intersection parameters and pretopology information.

#### Parameters

|             |                                |
|-------------|--------------------------------|
| <i>cv1</i>  | pointer to the first 2D curve  |
| <i>cv2</i>  | pointer to the second 2D curve |
| <i>epsg</i> | geometrical tolerance          |

#### Return values

|                      |                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>intersections</i> | this vector will contain the parameter pairs of the found intersections (one vector entry per intersection. The two parameters in the pair<> correspond to the parameter value in 'cv1' and 'cv2' for a particular intersection. |
| <i>pretopology</i>   | vector containing a pretopology indicator for each detected intersection point. There is one entry per intersection point.                                                                                                       |

28.1.4.73 `void Go::intersectCurvePoint ( const ParamCurve * crv, Point pnt, double epsge, std::vector< double > & intersections, std::vector< std::pair< double, double > > & int_crvs )`

28.1.4.74 `void Go::intersectCurves ( shared_ptr< ParamCurve > crv1, shared_ptr< ParamCurve > crv2, double tol, std::vector< std::pair< double, double > > & intersection_points )`

Intersection between two parametric curves.

28.1.4.75 `void Go::intersectcurves ( SplineCurve * cv1, SplineCurve * cv2, double epsge, std::vector< std::pair< double, double > > & intersections )`

Intersect two spline curves. Collect intersection parameters.

#### Parameters

|              |                                    |
|--------------|------------------------------------|
| <i>cv1</i>   | pointer to the first spline curve  |
| <i>cv2</i>   | pointer to the second spline curve |
| <i>epsge</i> | geometrical tolerance              |

#### Return values

|                      |                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>intersections</i> | this vector will contain the parameter pairs of the found intersections (one vector entry per intersection. The two parameters in the pair<> correspond to the parameter value in 'cv1' and 'cv2' for a particular intersection. |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

28.1.4.76 `void Go::intersectCurveSurf ( const SplineCurve * cv, const SplineSurface * sf, double epsge, std::vector< std::pair< double, Point > > & int_pts, std::vector< int > & pretopology, std::vector< std::pair< std::pair< double, Point >, std::pair< double, Point > > > & int_crvs )`

Intersect a spline curve and a spline surface.

28.1.4.77 `template<typename ValueType > bool Go::interval_overlap ( ValueType front1, ValueType back1, ValueType front2, ValueType back2 )`

Definition at line 151 of file checks.h.

28.1.4.78 `int Go::is_inside ( const std::vector< Go::Vector3D > & trim_curve_p, const std::vector< int > & contour, const double u, const double v )`

28.1.4.79 `int Go::is_on_contour ( const std::vector< Go::Vector3D > & trim_curve_p, const std::vector< int > & contour, const double u, const double v )`

28.1.4.80 `bool Go::is_on_corner ( const std::vector< Go::Vector3D > & trim_curve_p, const std::vector< int > & contour, const double u, const double v )`

28.1.4.81 `bool Go::link_is_iso ( shared_ptr< IntersectionLink > link )`

Definition at line 231 of file IntersectionPoolUtils.h.

28.1.4.82 `bool Go::link_is_iso_in ( shared_ptr< IntersectionLink > link, int dir )`

Definition at line 223 of file IntersectionPoolUtils.h.

28.1.4.83 `bool Go::link_is_iso_in_other_than ( shared_ptr< IntersectionLink > link, int dir )`

Definition at line 239 of file IntersectionPoolUtils.h.

28.1.4.84 `template<typename SquareMatrix > void Go::LUDecomp ( SquareMatrix & mat, int num_rows, int * perm, bool & parity )`

LU decomposition algorithm, based on Crout's algorithm

#### Parameters

|                 |                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------|
| <i>mat</i>      | The matrix to be decomposed. The actually used class must support the operation <code>[][]</code> and return 'double'. |
| <i>num_rows</i> | Number of rows (which is also equal to the number of columns).                                                         |
| <i>perm</i>     | Should point to an n-sized array where the permutation is written.                                                     |
| <i>parity</i>   | Value upon function completion is 'true' if the number of row interchanges was pair. 'false' otherwise.                |

Definition at line 52 of file LUDecomp\_implementation.h.

28.1.4.85 `template<typename SquareMatrix , typename T > void Go::LUSolveSystem ( SquareMatrix & A, int num_unknowns, T * vec )`

Solve the system  $Ax = b$  for  $x$ , using LU decomposition of the matrix  $A$ . Upon successful completion of the function, the matrix  $A$  will be LU decomposed, and the solution  $x$  will be computed and stored at the memory area pointed to by the last argument.

#### Parameters

|                     |                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>A</i>            | The system matrix $A$ . The actually used class must support the operation <code>[][]</code> and return 'double'.                                                                   |
| <i>num_unknowns</i> | Number of unknowns in the equation system.                                                                                                                                          |
| <i>vec</i>          | At function invocation, 'vec' should point to an array of $T$ , containing the vector 'b'. On successful completion of the function, this array will contain the solution for $x$ . |

Definition at line 132 of file LUDecomp\_implementation.h.

28.1.4.86 `shared_ptr<const CurveOnSurface> Go::make_curve_on_surface ( shared_ptr< const ParamSurface > surf, double u_start, double v_start, double u_end, double v_end, double p_start, double p_end )`

Definition at line 508 of file IntersectionPoolUtils.h.

28.1.4.87 `void Go::make_implicit_gauss ( std::vector< std::vector< double > > & mat, std::vector< double > & b )`

Performs implicitization using Gaussian elimination. This method is suitable when the implicitization is exact. If the implicitization is approximate, [make\\_implicit\\_svd\(\)](#) is better.

28.1.4.88 `void Go::make_implicit_svd ( std::vector< std::vector< double > > & mat, std::vector< double > & b, double & sigma_min )`

Performs implicitization using SVD. This method is suitable when the implicitization is approximate. If the implicitization is exact, [make\\_implicit\\_gauss\(\)](#) is better. Based on the function [SVD\(\)](#) from the newmat matrix library.

28.1.4.89 `void Go::make_matrix ( const SplineCurve & curve, int deg, std::vector< std::vector< double > > & mat )`

Make the matrix D.

28.1.4.90 `void Go::make_matrix ( const SplineSurface & surf, int deg, std::vector< std::vector< double > > & mat )`

Make the matrix D.

28.1.4.91 `void Go::make_matrix ( const PointCloud4D & cloud, int deg, std::vector< std::vector< double > > & mat )`

Make the matrix D.

28.1.4.92 `void Go::make_trimmed_mesh ( shared_ptr< ParamSurface > srf, std::vector< shared_ptr< ParamCurve > > & crv_set, std::vector< Vector3D > & vert, std::vector< Vector2D > & vert_p, std::vector< int > & bd, std::vector< Vector3D > & norm, std::vector< int > & mesh, std::vector< Vector3D > & trim_curve, std::vector< Vector3D > & trim_curve_p, const int dn, const int dm, double bd_res_ratio )`

28.1.4.93 `template<class Functor > void Go::minimise_conjugated_gradient ( FunctionMinimizer< Functor > & dfmin )`

This is the algorithm for minimising a function taking multiple parameters, using the conjugated gradient method. It is used in conjunction with the [FunctionMinimizer](#) class. Documentation for both can be found here: [FunctionMinimizer](#)  
Definition at line 78 of file `GeneralFunctionMinimizer_implementation.h`.

28.1.4.94 `bool Go::no_parent ( const shared_ptr< IntersectionPoint > & p )`

Definition at line 98 of file `IntersectionPoolUtils.h`.

28.1.4.95 `template<typename ValueType > bool Go::nondecreasing ( ValueType a, ValueType b, ValueType c )`

Definition at line 117 of file `checks.h`.

28.1.4.96 `template<typename ValueType > bool Go::nonincreasing ( ValueType a, ValueType b, ValueType c )`

Definition at line 125 of file `checks.h`.

28.1.4.97 `void Go::normalNoise ( double * res, double mean_err, int num_samples )`

Gives a certain number of random samples drawn from the normal distribution.

## Parameters

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <i>res</i>         | a pointer to the array where the resulting samples should be written.                           |
| <i>mean_err</i>    | the sigma parameter to the normal distribution.                                                 |
| <i>num_samples</i> | the desired number of samples (should also be the size of the array pointed to by <i>res</i> ). |

**28.1.4.98 Rational** `Go::operator* ( const Rational & r1, const Rational r2 )`

Definition at line 157 of file Rational.h.

Multiplication of a scalar with a polynomial.

Definition at line 273 of file BernsteinTetrahedralPoly.h.

28.1.4.109 **BernsteinMulti** `Go::operator*( const BernsteinMulti & m1, const BernsteinMulti & m2 )` `[inline]`

Multiplication of two polynomials.

Definition at line 300 of file BernsteinMulti.h.

28.1.4.110 **BernsteinMulti** `Go::operator*( const BernsteinMulti & m1, double c )` `[inline]`

Multiplication of a polynomial with a scalar.

Definition at line 310 of file BernsteinMulti.h.

28.1.4.111 **BernsteinMulti** `Go::operator*( double c, const BernsteinMulti & m1 )` `[inline]`

Multiplication of a scalar with a polynomial.

Definition at line 320 of file BernsteinMulti.h.

28.1.4.112 `template<typename T, int Dim> Go::Array<T, Dim> Go::operator* ( T d, const Go::Array< T, Dim > & v )`  
[inline]

The product of a vector and a scalar.

Definition at line 440 of file Array.h.

28.1.4.113 `Point Go::operator* ( double d, const Point & p )` [inline]

The product of a vector and a scalar.

Definition at line 539 of file Point.h.

28.1.4.114 `Rational Go::operator+ ( const Rational & r1, const Rational r2 )`

Definition at line 143 of file Rational.h.

28.1.4.115 `BernsteinPoly Go::operator+ ( const BernsteinPoly & p1, const BernsteinPoly & p2 )` [inline]

Addition of two polynomials.

Definition at line 230 of file BernsteinPoly.h.

28.1.4.116 `BernsteinPoly Go::operator+ ( double c, const BernsteinPoly & p )` [inline]

Addition of a scalar with a polynomial.

Definition at line 240 of file BernsteinPoly.h.

28.1.4.117 `BernsteinPoly Go::operator+ ( const BernsteinPoly & p, double c )` [inline]

Addition of a polynomial with a scalar.

Definition at line 250 of file BernsteinPoly.h.

28.1.4.118 `BernsteinTriangularPoly Go::operator+ ( const BernsteinTriangularPoly & p1, const BernsteinTriangularPoly & p2 )` [inline]

Addition of two polynomials.

Definition at line 255 of file BernsteinTriangularPoly.h.

28.1.4.119 `BernsteinTriangularPoly Go::operator+ ( double c, const BernsteinTriangularPoly & p )` [inline]

Addition of a scalar with a polynomial.

Definition at line 265 of file BernsteinTriangularPoly.h.

28.1.4.120 **BernsteinTriangularPoly** `Go::operator+ ( const BernsteinTriangularPoly & p, double c )` `[inline]`

Addition of a polynomial with a scalar.

Definition at line 275 of file BernsteinTriangularPoly.h.

28.1.4.121 **BernsteinTetrahedralPoly** `Go::operator+ ( const BernsteinTetrahedralPoly & p1, const BernsteinTetrahedralPoly & p2 )` `[inline]`

Addition of two polynomials.

Definition at line 283 of file BernsteinTetrahedralPoly.h.

28.1.4.122 **BernsteinTetrahedralPoly** `Go::operator+ ( double c, const BernsteinTetrahedralPoly & p )` `[inline]`

Addition of a scalar with a polynomial.

Definition at line 294 of file BernsteinTetrahedralPoly.h.

28.1.4.123 **BernsteinTetrahedralPoly** `Go::operator+ ( const BernsteinTetrahedralPoly & p, double c )` `[inline]`

Addition of a polynomial with a scalar.

Definition at line 304 of file BernsteinTetrahedralPoly.h.

28.1.4.124 **BernsteinMulti** `Go::operator+ ( const BernsteinMulti & m1, const BernsteinMulti & m2 )` `[inline]`

Addition of two polynomials.

Definition at line 330 of file BernsteinMulti.h.

28.1.4.125 **BernsteinMulti** `Go::operator+ ( const BernsteinMulti & m, double c )` `[inline]`

Addition of a polynomial with a scalar.

Definition at line 340 of file BernsteinMulti.h.

28.1.4.126 **BernsteinMulti** `Go::operator+ ( double c, const BernsteinMulti & m )` `[inline]`

Addition of a scalar with a polynomial.

Definition at line 350 of file BernsteinMulti.h.

28.1.4.127 **Rational** Go::operator- ( const Rational & r1, const Rational r2 )

Definition at line 150 of file Rational.h.

28.1.4.128 **BernsteinPoly** Go::operator- ( const BernsteinPoly & p1, const BernsteinPoly & p2 ) [inline]

Subtraction of two polynomials.

Definition at line 260 of file BernsteinPoly.h.

28.1.4.129 **BernsteinPoly** Go::operator- ( double c, const BernsteinPoly & p ) [inline]

Subtraction of a polynomial from a scalar.

Definition at line 270 of file BernsteinPoly.h.

28.1.4.130 **BernsteinPoly** Go::operator- ( const BernsteinPoly & p, double c ) [inline]

Subtraction of a scalar from a polynomial.

Definition at line 280 of file BernsteinPoly.h.

28.1.4.131 **BernsteinTriangularPoly** Go::operator- ( const BernsteinTriangularPoly & p1, const BernsteinTriangularPoly & p2 ) [inline]

Subtraction of two polynomials.

Definition at line 285 of file BernsteinTriangularPoly.h.

28.1.4.132 **BernsteinTriangularPoly** Go::operator- ( double c, const BernsteinTriangularPoly & p ) [inline]

Subtraction of a polynomial from a scalar.

Definition at line 295 of file BernsteinTriangularPoly.h.

28.1.4.133 **BernsteinTriangularPoly** Go::operator- ( const BernsteinTriangularPoly & p, double c ) [inline]

Subtraction of a scalar from a polynomial.

Definition at line 305 of file BernsteinTriangularPoly.h.

28.1.4.134 **BernsteinTetrahedralPoly** Go::operator- ( const BernsteinTetrahedralPoly & p1, const BernsteinTetrahedralPoly & p2 ) [inline]

Subtraction of two polynomials.

Definition at line 314 of file BernsteinTetrahedralPoly.h.

28.1.4.135 **BernsteinTetrahedralPoly** Go::operator- ( double *c*, const BernsteinTetrahedralPoly & *p* )  
[inline]

Subtraction of a polynomial from a scalar.

Definition at line 325 of file BernsteinTetrahedralPoly.h.

28.1.4.136 **BernsteinTetrahedralPoly** Go::operator- ( const BernsteinTetrahedralPoly & *p*, double *c* )  
[inline]

Subtraction of a scalar from a polynomial.

Definition at line 335 of file BernsteinTetrahedralPoly.h.

28.1.4.137 **BernsteinMulti** Go::operator- ( const BernsteinMulti & *m1*, const BernsteinMulti & *m2* ) [inline]

Subtraction of two polynomials.

Definition at line 360 of file BernsteinMulti.h.

28.1.4.138 **BernsteinMulti** Go::operator- ( const BernsteinMulti & *m*, double *c* ) [inline]

Subtraction of a scalar from a polynomial.

Definition at line 370 of file BernsteinMulti.h.

28.1.4.139 **BernsteinMulti** Go::operator- ( double *c*, const BernsteinMulti & *m* ) [inline]

Subtraction of a polynomial from a scalar.

Definition at line 380 of file BernsteinMulti.h.

28.1.4.140 **Rational** Go::operator/ ( const Rational & *r1*, const Rational *r2* )

Definition at line 164 of file Rational.h.

28.1.4.141 **BernsteinPoly** Go::operator/ ( const BernsteinPoly & *p*, double *c* ) [inline]

Division of a polynomial with a scalar.

Definition at line 290 of file BernsteinPoly.h.

28.1.4.142 **BernsteinTriangularPoly** Go::operator/ ( const BernsteinTriangularPoly & *p*, double *c* ) [inline]

Division of a polynomial with a scalar.

Definition at line 315 of file BernsteinTriangularPoly.h.

**28.1.4.143 BernsteinTetrahedralPoly** `Go::operator/ ( const BernsteinTetrahedralPoly & p, double c )`  
[inline]

Division of a polynomial with a scalar.

Definition at line 345 of file BernsteinTetrahedralPoly.h.

**28.1.4.144 BernsteinMulti** `Go::operator/ ( const BernsteinMulti & m, double c )` [inline]

Division of a polynomial with a scalar.

Definition at line 390 of file BernsteinMulti.h.

**28.1.4.145 bool** `Go::operator< ( const Point & p1, const Point & p2 )` [inline]

Less than operator.

Definition at line 551 of file Point.h.

**28.1.4.146 std::ostream&** `Go::operator<< ( std::ostream & os, const Go::Streamable & obj )` [inline]

Definition at line 79 of file Streamable.h.

**28.1.4.147 std::ostream&** `Go::operator<< ( std::ostream & os, const Rational & p )`

Definition at line 171 of file Rational.h.

**28.1.4.148 std::ostream&** `Go::operator<< ( std::ostream & os, const Go::BernsteinTriangularPoly & p )`  
[inline]

Write [BernsteinTriangularPoly](#) to output stream.

Definition at line 333 of file BernsteinTriangularPoly.h.

**28.1.4.149 std::ostream&** `Go::operator<< ( std::ostream & os, const Go::BernsteinTetrahedralPoly & p )`  
[inline]

Write [BernsteinTetrahedralPoly](#) to output stream.

Definition at line 363 of file BernsteinTetrahedralPoly.h.

**28.1.4.150 std::ostream&** `Go::operator<< ( std::ostream & os, const LRBSpline2D & b )` [inline]

Definition at line 374 of file LRBSpline2D.h.

28.1.4.151 `std::ostream& Go::operator<< ( std::ostream & os, const GPos & g )` `[inline]`

Definition at line 437 of file Mesh2D.h.

28.1.4.152 `std::ostream& Go::operator<< ( std::ostream & os, const Mesh2D & m )` `[inline]`

Definition at line 439 of file Mesh2D.h.

28.1.4.153 `template<typename T, int Dim> std::ostream& Go::operator<< ( std::ostream & os, const Go::Array< T, Dim > & v )` `[inline]`

Stream insertion for [Array](#).

Definition at line 450 of file Array.h.

28.1.4.154 `template<typename T, int Dim> std::ostream& Go::operator<< ( std::ostream & os, const MatrixXD< T, Dim > & m )` `[inline]`

output operator

Specialization of the determinant function for the 1x1 case. Terminates the [det\(\)](#) template recursion.

Definition at line 462 of file MatrixXD.h.

28.1.4.155 `std::ostream& Go::operator<< ( std::ostream & os, const Go::Point & v )` `[inline]`

Stream insertion for [Point](#).

Definition at line 547 of file Point.h.

28.1.4.156 `bool Go::operator==( const Point & p1, const Point & p2 )` `[inline]`

Equal operator.

Definition at line 563 of file Point.h.

28.1.4.157 `std::istream& Go::operator>> ( std::istream & is, Go::Streamable & obj )` `[inline]`

Definition at line 72 of file Streamable.h.

28.1.4.158 `std::istream& Go::operator>> ( std::istream & is, Go::BernsteinTriangularPoly & p )` `[inline]`

Read [BernsteinTriangularPoly](#) from input stream.

Definition at line 325 of file BernsteinTriangularPoly.h.

28.1.4.159 `std::istream& Go::operator>> ( std::istream & is, Go::BernsteinTetrahedralPoly & p )` `[inline]`

Read [BernsteinTetrahedralPoly](#) from input stream.

Definition at line 354 of file BernsteinTetrahedralPoly.h.

28.1.4.160 `std::istream& Go::operator>> ( std::istream & is, LRBSpline2D & b )` `[inline]`

Definition at line 375 of file LRBSpline2D.h.

28.1.4.161 `std::istream& Go::operator>> ( std::istream & is, GPos & g )` `[inline]`

Definition at line 438 of file Mesh2D.h.

28.1.4.162 `std::istream& Go::operator>> ( std::istream & is, Mesh2D & m )` `[inline]`

Definition at line 440 of file Mesh2D.h.

28.1.4.163 `template<typename T, int Dim> std::istream& Go::operator>> ( std::istream & is, Go::Array< T, Dim > & v )`  
`[inline]`

Stream extraction for [Array](#).

Definition at line 445 of file Array.h.

28.1.4.164 `std::istream& Go::operator>> ( std::istream & is, Go::Point & v )` `[inline]`

Stream extraction for [Point](#).

Definition at line 543 of file Point.h.

28.1.4.165 `bool Go::point_inside_contour ( const double x0, const double y0, const double *const vertices, const std::vector< int > & contour )`

28.1.4.166 `shared_ptr<boxStructuring::BoundingBoxStructure> Go::preProcessClosestVectors ( const std::vector< shared_ptr< GeomObject > > & surfaces, double par_len_el )`

Create preprocessing data for the closest vector calculations on a surface. `surfaces` - a collection of the parametric surfaces defining the surface model. Only instances of the [ParamSurface](#) subclass hierarchy are used `par_len_el` - a guiding for the side lengths of the segments in geometry space, used to determine the number of segments for elementary surfaces returns the preprocessing structures used as input for the closest point calculations

28.1.4.167 `double Go::quadrinomial ( int n, int i, int j, int k )` `[inline]`

computes the quadrinomial coefficient:  $n! / (i! j! k! (n-i-j-k)!)$

Definition at line 102 of file binom.h.

**28.1.4.168** `RegistrationResult Go::rawRegistration ( const std::vector< Point > & points_fixed, const std::vector< Point > & points_transform, bool allow_rescaling, RegistrationInput params )`

Given two sequences of points in 3D, get an approximate rotation, rescaling (optional) and translation that sends the second point set close to the first. The point sets should be close (but not necessarily identical) in shape, with matching points coming in the same order (i.e. point number *i* in the two sequences should be close to each other after performing the transformation on the second point set), but the original coordinate representation of the two sets might be totally different.

**28.1.4.169** `template<class T > void Go::Register ( )`

This function is used to register a class derived from [GeomObject](#) with the global [Factory](#). By using this function rather than [Factory::registerClass\(\)](#), the user does not have to worry about the details of the [Creator](#) class. To register a class

`DerivedClass`

, it should be sufficient to run:

```
Register<DerivedClass> ()
```

.

Definition at line 154 of file [Factory.h](#).

**28.1.4.170** `RegistrationResult Go::registration ( const std::vector< Point > & points_fixed, const std::vector< Point > & points_transform, bool allow_rescaling, RegistrationInput params )`

Given two sequences of points in 3D, get the rotation, rescaling (optional) and translation that sends the second point set as close as possible to the first (i.e. that minimizes the sum of the square distances). The sequences must be of same length (at least three), and the points will be matched in the order they come in the vectors, i.e. `points_transform[i]` should, after the transformation, be close to `points_fixed[i]`.

**28.1.4.171** `bool Go::segment_contour_intersection_for_s2m ( const double x0, const double y0, const double x1, const double y1, const double *const vertices, const std::vector< int > & contour, double & x, double & y, double & s, const bool snap_ends = false )`

**28.1.4.172** `template<typename T > T Go::signed_area ( const Array< T, 3 > * c, const Array< T, 3 > & normal )`

Computes the signed area of a triangle embedded in 3D space. Input is an array of corner points and a normal to determine the sign.

Definition at line 117 of file [Volumes.h](#).

**28.1.4.173** `template<typename T, int Dim> T Go::simplex_volume ( const Array< T, Dim > * a ) [inline]`

Computes the volume of a simplex consisting of (Dim+1) vertices embedded in Euclidean space of dimension (Dim)

Definition at line 77 of file [Volumes.h](#).

28.1.4.174 `template<typename Functor > double Go::simpsons_rule ( Functor & f, double a, double b, const double eps = 1.0e-6, const int max_iter = 20 )`

Routine to calculate the integral of the functor f from a to b using Simpson's rule.

Definition at line 84 of file Integration.h.

28.1.4.175 `template<typename Functor2D > double Go::simpsons_rule2D ( Functor2D & f, double ax, double bx, double ay, double by, const double eps = 1.0e-6, const int max_iter = 20 )`

Help functor to simpsons\_rule2D and gaussian\_quadrature2DRoutine to integrate the two-dimensional functor f over the rectangle defined by ax, bx, ay and by. Uses Simpson's rule.

Definition at line 161 of file Integration.h.

28.1.4.176 `SplineCurve GO_API* Go::SISLCurve2Go ( const SISLCurve *const cv )`

Convert a [SISLCurve](#) to a [SplineCurve](#)

Parameters

|                 |                          |
|-----------------|--------------------------|
| <code>cv</code> | the SISLCurve to convert |
|-----------------|--------------------------|

Returns

A newly generated [SplineCurve](#) that describes the same curve as 'cv'. The user assumes ownership and is responsible for cleaning up by calling the `delete` function.

28.1.4.177 `SplineSurface GO_API* Go::SISLSurf2Go ( SISLSurf * sf )`

Convert a SISLSurface to a [SplineSurface](#)

Parameters

|                 |                         |
|-----------------|-------------------------|
| <code>sf</code> | the SISLSurf to convert |
|-----------------|-------------------------|

Returns

A newly generated [SplineSurface](#) that describes the same surface as 'sf'. The user assumes ownership and is responsible for cleaning up by calling the `delete` function.

28.1.4.178 `std::vector< short_list_short_list > Go::sort_2dpoly_segments ( const double *const vertices, const std::vector< int > & contour, const bool transposed = false )`

28.1.4.179 `void Go::spline_to_bernstein ( const SplineCurve & seg, int dd, BernsteinPoly & bp )`

Takes a segment (defined as having numCoefs() == order() and an order()-regular knot vector) and returns a bernstein polynomial equal to the curve's coordinate number dd. Allowed values for dd are in [0, dimension()-1] for

nonrational segments, and in  $[0, \text{dimension}())$  for rational (NURBS) segments. The polynomials returned in the rational case are the weighted coordinate functions for  $dd$  in  $[0, \text{dimension}()-1]$  and to the weight polynomial for  $dd$  equal to  $\text{dimension}()$ .

28.1.4.180 `void Go::spline_to_bernstein ( const SplineSurface & pat, int dd, BernsteinMulti & bm )`

Converts the  $dd$ -component of a surface patch on [SplineSurface](#) form to a [BernsteinMulti](#)

28.1.4.181 `void Go::spline_to_bernstein ( const SplineCurve & seg, std::vector< BernsteinPoly > & seg_bp )`

Converts a curve segment on [SplineCurve](#) form to a vector of BernsteinPolys

28.1.4.182 `void Go::spline_to_bernstein ( const SplineSurface & pat, std::vector< BernsteinMulti > & pat_bm )`

Converts a surface patch on [SplineSurface](#) form to a vector of BernsteinMultis

28.1.4.183 `template<int Ndim> void Go::splineToBernstein ( const SplineCurve & segment, Array< BernsteinPoly, Ndim > & curve_bp )`

Converts a Bezier curve segment on [SplineCurve](#) form to an [Array](#) of  $Ndim$  BernsteinPolys. If the [SplineCurve](#) is rational,  $Ndim$  is equal to  $dim+1$ , where  $dim$  is the dimension of space. Furthermore, in  $curve\_bp$ , the weights are included in the space part of the coefficients, i.e. they have the form  $wP1, wP2, \dots, wPdim, w$ .

#### Parameters

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| <i>segment</i>  | the Bezier curve segment on <a href="#">SplineCurve</a> form |
| <i>curve_bp</i> | the resulting <a href="#">Array</a> of BernsteinPolys        |

Definition at line 96 of file BernsteinUtils.h.

28.1.4.184 `template<int Ndim> void Go::splineToBernstein ( const SplineSurface & patch, Array< BernsteinMulti, Ndim > & surface_bm )`

Converts a Bezier surface patch on [SplineSurface](#) form to an [Array](#) of  $Ndim$  BernsteinMultis. If the [SplineSurface](#) is rational,  $Ndim$  is equal to  $dim+1$ , where  $dim$  is the dimension of space. Furthermore, in  $surface\_bm$ , the weights are included in the space part of the coefficients, i.e. they have the form  $wP1, wP2, \dots, wPdim, w$ .

#### Parameters

|                   |                                                          |
|-------------------|----------------------------------------------------------|
| <i>patch</i>      | the Bezier surface on <a href="#">SplineSurface</a> form |
| <i>surface_bm</i> | the resulting <a href="#">Array</a> of BernsteinMultis   |

Definition at line 137 of file BernsteinUtils.h.

28.1.4.185 **double** Go::stepLenFromRadius ( *double radius*, *double aepsge* )

Computes the step length along a curve based on radius of curvature at a point on the curve, and an absolute tolerance.

28.1.4.186 **int** Go::stepLength ( *const std::vector< Point > & ft*, *const std::vector< Point > & gs*, *double delta*, *bool forward*, *double & delta\_t* )

28.1.4.187 **double** Go::stepLength ( *const std::vector< Point > & ft*, *const std::vector< Point > & gs*, *bool forward*, *std::vector< Point > & cvder*, *double min\_step*, *double max\_step*, *double aepsge* )

28.1.4.188 **template**<typename Iterator > **bool** Go::strictly\_decreasing ( Iterator *begin*, Iterator *end* )

Definition at line 88 of file checks.h.

28.1.4.189 **template**<typename Array > **bool** Go::strictly\_decreasing ( *const Array & A* )

Definition at line 95 of file checks.h.

28.1.4.190 **template**<typename ValueType > **bool** Go::strictly\_decreasing ( ValueType *a*, ValueType *b*, ValueType *c* )

Definition at line 133 of file checks.h.

28.1.4.191 **template**<typename Iterator > **bool** Go::strictly\_increasing ( Iterator *begin*, Iterator *end* )

Definition at line 58 of file checks.h.

28.1.4.192 **template**<typename Array > **bool** Go::strictly\_increasing ( *const Array & A* )

Definition at line 66 of file checks.h.

28.1.4.193 **template**<typename ValueType > **bool** Go::strictly\_increasing ( ValueType *a*, ValueType *b*, ValueType *c* )

Definition at line 141 of file checks.h.

28.1.4.194 **void** Go::systemSleep ( *double sleep\_time* )

Sleep for sleep\_time seconds.

28.1.4.195 **double** Go::tanLenFromRadius ( *double radius*, *double angle* )

To create the tangent length for interpolating a circular arc with an almost equi-oscillating Hermit cubic.

28.1.4.196 `template<typename Functor > void Go::trapezoidal ( Functor & f, double a, double b, double & s, int n )`

This routine computes the n'th stage of refinement of an extended trapezoidal rule. Used as a help routine for 'simpsons\_rule', found further down in this file. NB: It only carries out the computation for ONE stage of the procedure, so if you want to use it to integrate a function, you must call it successively for  $n = 1$ ,  $n = 2$ , ....

Definition at line 60 of file Integration.h.

28.1.4.197 `double Go::trinomial ( int n, int i, int j ) [inline]`

computes the trinomial coefficient:  $n! / (i! j! (n-i-j)!)$

Definition at line 92 of file binom.h.

28.1.4.198 `void Go::uniformNoise ( double * res, double lval, double uval, int num_samples )`

Gives a certain number of random samples drawn from the uniform distribution.

#### Parameters

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <i>res</i>         | a pointer to the array where the resulting samples should be written.                           |
| <i>lval</i>        | lower bound of the range from which the samples can take their values.                          |
| <i>uval</i>        | upper bound of the range from which the samples can take their values.                          |
| <i>num_samples</i> | the desired number of samples (should also be the size of the array pointed to by <i>res</i> ). |

28.1.4.199 `template<typename T > T Go::volume ( const Array< T, 3 > * c ) [inline]`

Computes the volume of a 3D simplex (embedded in 3D space).

Definition at line 110 of file Volumes.h.

28.1.4.200 `template<typename Iterator > bool Go::weakly_decreasing ( Iterator begin, Iterator end )`

Definition at line 102 of file checks.h.

28.1.4.201 `template<typename Array > bool Go::weakly_decreasing ( const Array & A )`

Definition at line 109 of file checks.h.

28.1.4.202 `template<typename Iterator > bool Go::weakly_increasing ( Iterator begin, Iterator end )`

Definition at line 74 of file checks.h.

28.1.4.203 `template<typename Array > bool Go::weakly_increasing ( const Array & A )`

Definition at line 81 of file checks.h.

28.1.4.204 `void Go::writePostscriptMesh ( Go::LRSplineSurface & lr_spline_sf, std::ostream & out, const bool close = true )`

## 28.1.5 Variable Documentation

28.1.5.1 `const int Go::MAJOR_VERSION = 1`

Definition at line 51 of file GeomObject.h.

28.1.5.2 `const int Go::MINOR_VERSION = 0`

Definition at line 52 of file GeomObject.h.

## 28.2 Go::AdaptSurface Namespace Reference

### Functions

- `shared_ptr< SplineSurface > approxInSplineSpace (shared_ptr< ParamSurface > surf, shared_ptr< SplineSurface > surf2, double tol)`

### 28.2.1 Detailed Description

This namespace contains functions for generating SplineSurfaces by approximation, etc.

### 28.2.2 Function Documentation

**28.2.2.1** `shared_ptr<SplineSurface> Go::AdaptSurface::adaptSurface ( shared_ptr< ParamSurface > surf, shared_ptr< SplineSurface > init_surf, double tol )`

Adapt the initial surface, `init_surf`, to the surface, `surf`, within the given tolerance, `tol`. The spline space of the initial surface may be refined

**28.2.2.2** `shared_ptr<SplineSurface> Go::AdaptSurface::approxInSplineSpace ( shared_ptr< ParamSurface > surf, shared_ptr< SplineSurface > surf2, double tol )`

Approximate `surf1` within the tolerance `tol` in the spline space of `surf2` or in a refinement of this spline space.

**28.2.2.3** `void Go::AdaptSurface::createTriangulation ( shared_ptr< ParamSurface > surf, const RectDomain & dom, shared_ptr< ftPointSet > & points, vector< int > & corner, bool consider_joint = true, int nmb = -1 )`

Fetch data and create triangulation.

**28.2.2.4** `std::vector<shared_ptr<SplineCurve>> Go::AdaptSurface::curveApprox ( shared_ptr< ParamCurve > cvs[], int nmb_cvs, const BsplineBasis & init_basis, double tol )`

Approximate a number of curves in the same spline space given an initial spline space that may be refined. The approximation tolerance is `tol`. This function is an interface to the function [CurveCreators::curveApprox](#) in `gotools-core` creators

**28.2.2.5** `std::vector<shared_ptr<SplineCurve>> Go::AdaptSurface::curveApprox ( shared_ptr< ParamCurve > cvs[], int nmb_cvs, double tol, double degree = 3 )`

Approximate a number of curves in the same spline space. The approximation tolerance is `tol` This function is an interface to the function [CurveCreators::curveApprox](#) in `gotools-core` creators

**28.2.2.6** `shared_ptr<SplineSurface> Go::AdaptSurface::doApprox ( shared_ptr< SplineSurface > init_surf, int max_iter, shared_ptr< ftPointSet > points, double tol, double & max_error, double & mean_error )`

Given an initial spline space and a point set, perform maximum `max_iter` iterations to approximate the points within the tolerance `tol`. The maximum and average error in the given points are returned.

**28.2.2.7** `std::vector<shared_ptr<SplineSurface>> Go::AdaptSurface::expressInSameSplineSpace ( shared_ptr< ParamSurface > surf1, shared_ptr< ParamSurface > surf2, double tol )`

Approximate the surfaces `surf1` and `surf2` in the same spline space with approximation errors less than `tol`

28.2.2.8 `void Go::AdaptSurface::getBoundaryData ( shared_ptr< ParamSurface > surf, const RectDomain & dom, int nmb_sample, shared_ptr< ftPointSet > points, std::vector< int > & corner )`

Fetch data points at the boundaries a the surface surf. To be used in surface approximation

28.2.2.9 `bool Go::AdaptSurface::getCornerCorrespondance ( shared_ptr< ParamSurface > surf1, shared_ptr< ParamSurface > surf2, int & idx, bool & turned )`

Compute the correspondance between corners in the surfaces surf1 and surf2. This function is used from approxInSplineSpace and expressInSameSplineSpace

28.2.2.10 `void Go::AdaptSurface::getInnerData ( shared_ptr< ParamSurface > surf, const RectDomain & dom, int nmb_sample, shared_ptr< ftPointSet > points, bool consider_joint = true )`

Fetch data points in the inner of the surface surf. To be used in surface approximation

28.2.2.11 `double Go::AdaptSurface::parameterizePoints ( shared_ptr< SplineSurface > init_surf, shared_ptr< ftPointSet > points, std::vector< int > corner )`

Parameterize the point set points with respect to the surface init\_surf. To be used in surface approximation.

28.2.2.12 `double Go::AdaptSurface::projectPoints ( shared_ptr< SplineSurface > surf, shared_ptr< ftPointSet > points )`

Parameterize by projection.

28.2.2.13 `void Go::AdaptSurface::updatePointTopology ( shared_ptr< ParamSurface > surf, ftPointSet & points )`

Compute point set topology.

## 28.3 Go::BoundedUtils Namespace Reference

### 28.3.1 Detailed Description

Functions related to the trimming of surfaces, etc. Also contains functions for spatial transformations of such surfaces (rotation, translation, etc.)

### 28.3.2 Function Documentation

28.3.2.1 `int Go::BoundedUtils::checkAndFixLoopOrientation ( shared_ptr< BoundedSurface > surf )`

Check loop orientation and fix if necessary. NB! It is assumed that the loops has got the correct sequence

#### Parameters

|             |                                             |
|-------------|---------------------------------------------|
| <i>surf</i> | the <a href="#">BoundedSurface</a> to check |
|-------------|---------------------------------------------|

#### Returns

`true` if the loop orientation was fixed, `false` otherwise

28.3.2.2 `int Go::BoundedUtils::checkCurveCoincidence ( shared_ptr< CurveOnSurface > cv1, shared_ptr< CurveOnSurface > cv2, double tol, bool same_orient )`

Help function for `getBoundaryLoops`.

28.3.2.3 `BoundedSurface* Go::BoundedUtils::convertToBoundedSurface ( const SplineSurface & surf, double space_epsilon )`

If `surf` already is a [BoundedSurface](#), return clone. If [SplineSurface](#), convert. Otherwise, Error. Return surface is created inside function. Convert a [SplineSurface](#) to a [BoundedSurface](#). All information is copied, nothing is shared.

#### Parameters

|                      |                                                                            |
|----------------------|----------------------------------------------------------------------------|
| <i>surf</i>          | the <a href="#">SplineSurface</a> to convert                               |
| <i>space_epsilon</i> | the tolerance assigned to the newly created <a href="#">BoundedSurface</a> |

#### Returns

(pointer to) a [BoundedSurface](#) that represent the same surface as 'surf'. The user assumes ownership of the object.

28.3.2.4 `bool Go::BoundedUtils::createMissingParCvs ( Go::BoundedSurface & bd_sf )`

28.3.2.5 `bool Go::BoundedUtils::createMissingParCvs ( std::vector< Go::CurveLoop > & bd_loops )`

28.3.2.6 `std::vector<shared_ptr<BoundedSurface>> Go::BoundedUtils::createTrimmedSurfs ( std::vector<std::vector<shared_ptr<CurveOnSurface>>> & loops, shared_ptr<ParamSurface> under_sf, double epsgeo )`

All input loops are expected to be simple, lying on surface. They are sorted based on orientation. No pair of curves with the same orientation may lie inside/outside each other. If they do the outer/inner (ccw/cw) loop(s) will be erased. Furthermore assuming no pair of loops intersect (may touch tangentially). Define the surfaces that result from trimming a given [SplineSurface](#) with a set of boundary loops. Counterclockwise loops define the interior of a parameter domain, while clockwise loops define holes in the domain. Method assumes all parameter curves exist.

#### Parameters

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>loops</i>    | each entry in the outermost vector represent a vector of curves that together specify a loop in 2D parametrical space of the surface 'under_sf'. These are the trim curves. The curves are expected to be simple, lying on the surface 'under_sf'. No pair of curve loops with the same orientation may lie inside/outside of each other; in that case, the irrelevant loop will be erased. Furthermore, we assume that no pair of loops intersect transversally (they are still allowed to touch tangentially). |
| <i>under_sf</i> | the underlying <a href="#">SplineSurface</a> that we are going to trim with the curves given in 'loops'.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>epsgeo</i>   | geometrical tolerance used in computations                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

#### Returns

a vector containing [BoundedSurface](#) s that each represent a trimmed part of the 'under\_sf' surface.

28.3.2.7 `void Go::BoundedUtils::fixInvalidBoundedSurface ( shared_ptr<Go::BoundedSurface> & bd_sf, double max_tol_mult = 1.0 )`

Fix the boundary loops of a surface in case of inconsistencies.

28.3.2.8 `std::vector<std::vector<shared_ptr<CurveOnSurface>>> Go::BoundedUtils::getBoundaryLoops ( const BoundedSurface & sf, std::vector<shared_ptr<CurveOnSurface>> & part_bnd_cvs, double eps, int last_split = -1 )`

Given input of partial boundary curves, extract parts of boundary making it a boundary loop (or more). Input segments expected to be ordered, going in the same direction. *part\_bnd\_cvs* should lie on *sf* (as opposed to only parts of *cvs*). This function tries to complete "partial" boundary loops by filling out the missing parts using fragments from the domain boundary of a [BoundedSurface](#).

#### Parameters

|                     |                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <i>sf</i>           | the surface whose domain boundary will be used                                                                                      |
| <i>part_bnd_cvs</i> | a vector of (shared pointers to) curve segments that represent incomplete loops. Upon function return, this vector will be emptied. |

#### Returns

a vector contained the loops that the function was able to completely close using curve segments from '*part\_bnd\_cvs*' and the domain boundaries of '*sf*'.

28.3.2.9 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::getCylinderIntersections ( const shared_ptr< ParamSurface > & surf, Point point, Point axis, double radius, double epsge, shared_ptr< BoundedSurface > & bounded_sf )`

Intersect a parametric surface with a cylinder and fetch the intersections curves represented as curve on surface

28.3.2.10 `void Go::BoundedUtils::getIntersectionCurve ( shared_ptr< ParamSurface > & sf1, shared_ptr< ParamSurface > & sf2, std::vector< shared_ptr< CurveOnSurface >> & int_segments1, std::vector< shared_ptr< CurveOnSurface >> & int_segments2, double epsge )`

Find the intersction curve(s) between two spline surfaces

#### Parameters

|                  |                                 |
|------------------|---------------------------------|
| <code>sf1</code> | the first surface to intersect  |
| <code>sf2</code> | the second surface to intersect |

#### Return values

|                            |                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| <code>int_segments1</code> | a vector of <a href="#">CurveOnSurface</a> s, representing the intersection curves as lying on 'sf1'. |
| <code>int_segments2</code> | a vector of <a href="#">CurveOnSurface</a> s, representing the intersection curves as lying on 'sf2'. |

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <code>epsge</code> | geometrical tolerance to be used for intersection computations |
|--------------------|----------------------------------------------------------------|

28.3.2.11 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::getPlaneIntersections ( const shared_ptr< ParamSurface > & surf, Point point, Point normal, double epsge, shared_ptr< BoundedSurface > & bounded_sf )`

Intersect a parametric surface with a plane and fetch the intersections curves represented as curve on surface

28.3.2.12 `void Go::BoundedUtils::getSurfaceIntersections ( const shared_ptr< ParamSurface > & surf1, const shared_ptr< ParamSurface > & surf2, double epsge, std::vector< shared_ptr< CurveOnSurface >> & int_cv1, shared_ptr< BoundedSurface > & bounded_sf1, std::vector< shared_ptr< CurveOnSurface >> & int_cv2, shared_ptr< BoundedSurface > & bounded_sf2 )`

Intersect two parametric surfaces and fetch the resulting intersection curves represented as curve on surface

28.3.2.13 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::getTrimCrvsParam ( const shared_ptr< ParamSurface > & surf, Point parval1, Point parval2, double epsge, shared_ptr< BoundedSurface > & bounded_sf )`

Get the split curves between specified parameter values.

28.3.2.14 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::getTrimCrvsPcrv ( const shared_ptr<ParamSurface> & surf, shared_ptr<ParamCurve> & pcurve, double epsge, shared_ptr<BoundedSurface> & bounded_sf )`

28.3.2.15 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::intersectWithCylinder ( shared_ptr<ParamSurface> & surf, Point pnt, Point vec, double radius, double geom_tol )`

Find the intersection curve(s) between a [SplineSurface](#) and a given cylinder. The cylinder is defined by a point on the axis, the axis direction and the radius

#### Parameters

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <i>surf</i>     | the <a href="#">SplineSurface</a> to intersect with the cylinder |
| <i>pnt</i>      | a point lying on the cylinder axis                               |
| <i>vec</i>      | is the direction of the cylinder axis is the cylinder radius     |
| <i>geom_tol</i> | geometrical tolerance to be used for intersection computations   |

#### Returns

a vector with (shared pointers to) [CurveOnSurface](#) s, which represent the intersection curves found.

28.3.2.16 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::intersectWithPlane ( shared_ptr<ParamSurface> & surf, Point pnt, Point normal, double geom_tol )`

Find the intersection curve(s) between a [SplineSurface](#) and a given plane. The plane is defined by its normal and a point on the plane.

#### Parameters

|                 |                                                                |
|-----------------|----------------------------------------------------------------|
| <i>surf</i>     | the <a href="#">SplineSurface</a> to intersect with the plane  |
| <i>pnt</i>      | a point lying on the plane                                     |
| <i>normal</i>   | the normal of the plane                                        |
| <i>geom_tol</i> | geometrical tolerance to be used for intersection computations |

#### Returns

a vector with (shared pointers to) [CurveOnSurface](#) s, which represent the intersection curves found.

28.3.2.17 `std::vector<shared_ptr<CurveOnSurface>> Go::BoundedUtils::intersectWithSurface ( CurveOnSurface & curve, BoundedSurface & bounded_surf, double epsge )`

Extract those parts of a given [CurveOnSurface](#) where its parameter curve lies inside the parameter domain of a [BoundedSurface](#).

#### Parameters

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| <i>curve</i>        | the <a href="#">CurveOnSurface</a> that we want to check                        |
| <i>bounded_surf</i> | the <a href="#">BoundedSurface</a> whose parameter domain we will check against |
| <i>epsge</i>        | geometric tolerance used in calculations                                        |

**Returns**

a vector containing those segments of 'curve' that have parameter descriptions inside the parameter domain of the 'bounded\_surf'.

```
28.3.2.18 void Go::BoundedUtils::intersectWithSurfaces (std::vector< shared_ptr< CurveOnSurface > > & curves1,
shared_ptr< BoundedSurface > & bd_sf1, std::vector< shared_ptr< CurveOnSurface > > & curves2,
shared_ptr< BoundedSurface > & bd_sf2, double epsge)
```

We have two set of [CurveOnSurface](#) s, 'curves1' and 'curves2', and two [BoundedSurface](#) s, 'bd\_sf1' and 'bd\_sf2'. We extract those segments of curves in 'curves1' and 'curves2' that have parameter curves in the parameter domains of respective 'bd\_sf1' and 'bd\_sf2'. Then we compare the resulting segments from the two sets against each others, and keep those that overlap spatially. Segments are split in two if necessary in order to make start and end points from one set coincide with those from the other set. 'curves1' and 'curves2' are then cleared and filled with the resulting curve segments.

**Parameters**

|                |                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------|
| <i>curves1</i> | see above, we suppose that the curves are NOT self-intersecting                                                  |
| <i>bd_sf1</i>  | see above, we suppose that the underlying surface is the same as the one referred to by the curves in 'curves1'. |
| <i>curves2</i> | see above, we suppose that the curves are NOT self-intersecting                                                  |
| <i>bd_sf2</i>  | see above, we suppose that the underlying surface is the same as the one referred to by the curves in 'curves2'. |
| <i>epsge</i>   | geometric epsilon used in closest point calculations, checks for coincidence, etc.                               |

```
28.3.2.19 bool Go::BoundedUtils::loopsDegenerate (std::vector< shared_ptr< CurveOnSurface > > & loop, double
epsgeo)
```

Check if the distance between two curves in the loop is less than the tolerance epsgeo. Common endpoints between curves are not counted.

```
28.3.2.20 shared_ptr<Go::SplineSurface> Go::BoundedUtils::makeTrimmedPlane (shared_ptr< Go::Plane > & plane,
std::vector< shared_ptr< Go::ParamCurve > > & space_crvs)
```

Create spline surface description of plane. The plane should be bounded according to the space\_crvs (which should lie in the plane).

**Parameters**

|                   |                             |
|-------------------|-----------------------------|
| <i>plane</i>      |                             |
| <i>space_crvs</i> | Curves lying in the plane,. |

**Returns**

Spline surface description of a bounded plane.

28.3.2.21 void Go::BoundedUtils::rotateBoundedSurf ( Point *rot\_axis*, double *alpha*, BoundedSurface & *bf\_sf*, double *deg\_eps* )

## Parameters

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <i>rot_axis</i> | a vector specifying the axis of rotation                         |
| <i>alpha</i>    | the angle of rotation (in radians)                               |
| <i>bf_sf</i>    | the surface to rotate                                            |
| <i>deg_eps</i>  | an epsilon value used when determining degenerate boundary loops |

28.3.2.22 std::vector<shared\_ptr<BoundedSurface>> Go::BoundedUtils::splitBetweenParams ( const shared\_ptr<ParamSurface> & *surf*, Point *parval1*, Point *parval2*, double *epsge* )

Split a parametric surface between specified parameter values.

28.3.2.23 std::vector<shared\_ptr<BoundedSurface>> Go::BoundedUtils::splitBetweenParPairs ( const shared\_ptr<ParamSurface> & *surf*, std::vector<std::pair<Point, Point>> *parvals*, double *epsge* )

28.3.2.24 std::vector<shared\_ptr<BoundedSurface>> Go::BoundedUtils::splitWithPlane ( const shared\_ptr<ParamSurface> & *surf*, Point *point*, Point *normal*, double *epsge* )

Split a parametric surface by intersecting it with a plane and split along intersection curves

28.3.2.25 std::vector<shared\_ptr<BoundedSurface>> Go::BoundedUtils::splitWithTrimSegments ( shared\_ptr<BoundedSurface> & *surf*, std::vector<shared\_ptr<CurveOnSurface>> & *bnd\_cvs*, double *eps* )

Split a given bounded surface according to given trimming curves in this surface Notice that the function expects the given curves to actually split the surface

28.3.2.26 std::vector<shared\_ptr<BoundedSurface>> Go::BoundedUtils::subtractSfPart ( shared\_ptr<BoundedSurface> & *surf*, std::vector<shared\_ptr<CurveOnSurface>> & *bnd\_cvs*, double *eps* )

Subtract the part of a trimmed surface corresponding to a given boundary loop from the surface and return the remaining pieces

28.3.2.27 void Go::BoundedUtils::translateBoundedSurf ( Point *trans\_vec*, BoundedSurface & *bd\_sf*, double *deg\_eps* )

Translate a given [BoundedSurface](#)

## Parameters

|                  |                                                                  |
|------------------|------------------------------------------------------------------|
| <i>trans_vec</i> | the vector specifying the translation to apply to the surface    |
| <i>bd_sf</i>     | the surface to translate                                         |
| <i>deg_eps</i>   | an epsilon value used when determining degenerate boundary loops |

28.3.2.28 `void Go::BoundedUtils::translatePlaneToCurves ( shared_ptr< Go::Plane > & plane, std::vector< shared_ptr< Go::ParamCurve > > & space_crvs )`

Change the position of a plane to adapt it to curves supposed to lie in this plane. Geometry fix related to external models

28.3.2.29 `void Go::BoundedUtils::trimSurfaceKinks ( const BoundedSurface & sf, double max_normal_angle, std::vector< double > & g1_disc_u, std::vector< double > & g1_disc_v, bool compute_g1_disc = true )`

Surface assumed to be continuous. Return parameter values failing to achieve G1-continuity.

28.3.2.30 `std::vector<std::vector<shared_ptr<BoundedSurface>>> Go::BoundedUtils::trimSurfsWithSurfs ( const std::vector< shared_ptr< ParamSurface > > & sfs1, const std::vector< shared_ptr< ParamSurface > > & sfs2, double epsge )`

28.3.2.31 `std::vector<shared_ptr<BoundedSurface>> Go::BoundedUtils::trimSurfWithSurf ( const shared_ptr< ParamSurface > & sf1, const shared_ptr< ParamSurface > & sf2, double epsge )`

must be BoundedSurfaces or [SplineSurface](#) underlying surfaces must be of type [SplineSurface](#) If the argument surfaces intersect, and if the intersection curves result in new boundary loops being defined, then the new surface parts defined within these domains will be returned. Otherwise, the return vector will be empty.

#### Parameters

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>sf1</i>   | the first surface to participate in the intersection  |
| <i>sf2</i>   | the second surface to participate in the intersection |
| <i>epsge</i> | geometrical tolerance to be used in computations      |

#### Returns

a vector with the surfaces representing the parts of the original surfaces enclosed by new parametrical loops arising when combining existing loops with the curves defined by the intersection.

28.3.2.32 `std::vector<shared_ptr<BoundedSurface>> Go::BoundedUtils::trimWithPlane ( const shared_ptr< ParamSurface > & surf, Point point, Point normal, double epsge )`

We intersect a parametric surface with a plane, and return the surface(s) consisting only of the part(s) of the surface that were located on the positive side of the intersection. If there was no intersection, an empty stl-vector is returned. The plane is defined by its normal and a point located on it.

#### Parameters

|               |                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------|
| <i>surf</i>   | the parametric surface. It must be either a <a href="#">BoundedSurface</a> or a <a href="#">SplineSurface</a> . |
| <i>point</i>  | a point on the plane to intersect against                                                                       |
| <i>normal</i> | normal of the plane to intersect against                                                                        |
| <i>epsge</i>  | geometric tolerance                                                                                             |

**Returns**

the surface(s) consisting of the part(s) of 'surf' that were located on the positive side of the intersection.

## 28.4 Go::boxStructuring Namespace Reference

**Classes**

- class [BoundingBoxStructure](#)
- class [SubSurfaceBoundingBox](#)
- class [SurfaceData](#)

### 28.4.1 Detailed Description

Namespace for preprocessing structures on a surface model used to speed up closest point calculations. It consists of three classes:

- [BoundingBoxStructure](#), the overall class where one instance holds the entire preprocess structure data
- [SurfaceData](#), one instance for each surface in the surface model
- [SubSurfaceBoundingBox](#), holding preprocessed data for one specific rectangular segment in a tensor mesh sub structure of the parameter space on a surface (the underlying surface in case of a [BoundedSurface](#))

## 28.5 Go::ClosestPoint Namespace Reference

Namespace for computing closest points.

**Functions**

- void [closestPtCurves2D](#) ([ParamCurve](#) \*cv1, [ParamCurve](#) \*cv2, [double](#) aepsge, [double](#) tmin1, [double](#) tmax1, [double](#) tmin2, [double](#) tmax2, [double](#) seed1, [double](#) seed2, int method, [bool](#) quick, [double](#) &par1, [double](#) &par2, [double](#) &dist, [Point](#) &ptc1, [Point](#) &ptc2, int &istat)

## 28.5.1 Detailed Description

Namespace for computing closest points.

## 28.5.2 Function Documentation

**28.5.2.1** void Go::ClosestPoint::closestPtCurves ( const ParamCurve \* *cv1*, const ParamCurve \* *cv2*, double & *par1*, double & *par2*, double & *dist*, Point & *ptc1*, Point & *ptc2* )

Compute a closest point or an intersection point between two curves. Ported from the sisl-functions s1770, s1770↔\_s9corr, s1770\_s9dir

### Parameters

|            |                   |
|------------|-------------------|
| <i>cv1</i> | Curve number one. |
| <i>cv2</i> | Curve number two. |

### Return values

|             |                                              |
|-------------|----------------------------------------------|
| <i>par1</i> | Parameter value of the first curve's point.  |
| <i>par2</i> | Parameter value of the second curve's point. |
| <i>dist</i> | Distance between the points.                 |
| <i>ptc1</i> | <a href="#">Point</a> on curve number one.   |
| <i>ptc2</i> | <a href="#">Point</a> on curve number two.   |

**28.5.2.2** void Go::ClosestPoint::closestPtCurves ( const ParamCurve \* *cv1*, const ParamCurve \* *cv2*, double *tmin1*, double *tmax1*, double *tmin2*, double *tmax2*, double *seed1*, double *seed2*, double & *par1*, double & *par2*, double & *dist*, Point & *ptc1*, Point & *ptc2* )

Newton iteration on the distance function between two curves to find a closest point or an intersection point. The solution is restricted to the intervals [*tmin1*,*tmax1*] and [*tmin2*,*tmax2*] in the first and second curves's parameter domain. Ported from the sisl function s1770.

### Parameters

|              |                                                   |
|--------------|---------------------------------------------------|
| <i>cv1</i>   | Curve number one.                                 |
| <i>cv2</i>   | Curve number two.                                 |
| <i>tmin1</i> | Min. parameter value. First curve                 |
| <i>tmax1</i> | Max. parameter value. First curve                 |
| <i>tmin2</i> | Min. parameter value. Second curve                |
| <i>tmax2</i> | Max. parameter value. Second curve                |
| <i>seed1</i> | Start point for iteration along curve number one. |
| <i>seed2</i> | Start point for iteration along curve number two. |

### Return values

|             |                                             |
|-------------|---------------------------------------------|
| <i>par1</i> | Parameter value of the first curve's point. |
|-------------|---------------------------------------------|

## Return values

|             |                                              |
|-------------|----------------------------------------------|
| <i>par2</i> | Parameter value of the second curve's point. |
| <i>dist</i> | Distance between the points.                 |
| <i>ptc1</i> | <a href="#">Point</a> on curve number one.   |
| <i>ptc2</i> | <a href="#">Point</a> on curve number two.   |

28.5.2.3 void Go::ClosestPoint::closestPtCurves2D ( ParamCurve \* *cv1*, ParamCurve \* *cv2*, double *aepsge*, double *tmin1*, double *tmax1*, double *tmin2*, double *tmax2*, double *seed1*, double *seed2*, int *method*, bool *quick*, double & *par1*, double & *par2*, double & *dist*, Point & *ptc1*, Point & *ptc2*, int & *istat* )

Newton iteration on the distance function between two curves in 2D to find a closest point or an intersection point. The solution is restricted to the intervals [*tmin1*,*tmax1*] and [*tmin2*,*tmax2*] in the first and second curves's parameter domain. Ported from the sisl-function `s1770_2D`.

## Parameters

|               |                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cv1</i>    | Curve number one.                                                                                                                                                  |
| <i>cv2</i>    | Curve number two.                                                                                                                                                  |
| <i>aepsge</i> | Geometry resolution.                                                                                                                                               |
| <i>tmin1</i>  | Min. parameter value. First curve                                                                                                                                  |
| <i>tmax1</i>  | Max. parameter value. First curve                                                                                                                                  |
| <i>tmin2</i>  | Min. parameter value. Second curve                                                                                                                                 |
| <i>tmax2</i>  | Max. parameter value. Second curve                                                                                                                                 |
| <i>seed1</i>  | Start point for iteration along curve number one.                                                                                                                  |
| <i>seed2</i>  | Start point for iteration along curve number two.                                                                                                                  |
| <i>method</i> | 1 or 2. Using the the method in <code>s1770_2D</code> , starting with order one or two. <code>method=3</code> uses the method from <code>s1770</code> (order one). |
| <i>quick</i>  | Reduce requirement on exactness.                                                                                                                                   |

## Return values

|              |                                                      |
|--------------|------------------------------------------------------|
| <i>par1</i>  | Parameter value of the first curve's point.          |
| <i>par2</i>  | Parameter value of the second curve's point.         |
| <i>dist</i>  | Distance in space between the points.                |
| <i>ptc1</i>  | <a href="#">Point</a> on curve number one.           |
| <i>ptc2</i>  | <a href="#">Point</a> on curve number two.           |
| <i>istat</i> | =1 Intersection. =2 Minimum value. =3 Nothing found. |

28.5.2.4 void Go::ClosestPoint::closestPtCurveSurf ( ParamCurve \* *pcurve*, ParamSurface \* *psurf*, double *aepsge*, double *astart1*, double *aend1*, RectDomain \* *domain*, double *anext1*, double *enext2*[], double & *cpos1*, double *gpos2*[], double & *dist*, Point & *pt\_cv*, Point & *pt\_su*, bool *second\_order* = false )

Newton iteration on the distance function between a curve and a surface to find a closest point or an intersection point. The solution is restricted to the interval [*astart1*,*aend1*] in the curves's parameter domain and [*estart2*[],*eend2*[][]] in the surface's parameter domain. Ported from the sisl-function `s1772`.

## Parameters

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| <i>pcurve</i>       | Pointer to the curve in the intersection.                           |
| <i>psurf</i>        | Pointer to the surface in the intersection.                         |
| <i>aepsge</i>       | Geometry resolution.                                                |
| <i>astart1</i>      | Start parameter value of the curve.                                 |
| <i>aend1</i>        | End parameter value of the curve.                                   |
| <i>domain</i>       | the parametric domain of interest of the surface                    |
| <i>anext1</i>       | Start point for iteration along curve number one.                   |
| <i>enext2[]</i>     | Start parameter values of the iteration on the surface.             |
| <i>second_order</i> | if 'true' the function will attempt a second-order method directly. |

## Return values

|                |                                                            |
|----------------|------------------------------------------------------------|
| <i>cpos1</i>   | Parameter value of the curve in the intersection point.    |
| <i>gpos2[]</i> | Parameter values of the surface in the intersection point. |
| <i>dist</i>    | Distance between the points.                               |
| <i>pt_cv</i>   | The point on the curve.                                    |
| <i>pt_su</i>   | The point on the surface.                                  |

28.5.2.5 void Go::ClosestPoint::closestPtCurveSurf ( ParamCurve \* *pcurve*, ParamSurface \* *psurf*, double *aepsge*, double *astart1*, double *estart2[]*, double *aend1*, double *eend2[]*, double *anext1*, double *enext2[]*, double & *cpos1*, double *gpos2[]*, double & *dist*, Point & *pt\_cv*, Point & *pt\_su*, int & *istat*, bool *second\_order* = false )

Newton iteration on the distance function between a curve and a surface to find a closest point or an intersection point. The solution is restricted to the interval [*astart1*,*aend1*] in the curves's parameter domain and [*estart2[]*,*eend2[]*] in the surface's parameter domain. Ported from the sisl-function `s1772`.

## Parameters

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| <i>pcurve</i>       | Pointer to the curve in the intersection.                           |
| <i>psurf</i>        | Pointer to the surface in the intersection.                         |
| <i>aepsge</i>       | Geometry resolution.                                                |
| <i>astart1</i>      | Start parameter value of the curve.                                 |
| <i>estart2[]</i>    | Start parameter values of surface.                                  |
| <i>aend1</i>        | End parameter value of the curve.                                   |
| <i>eend2[]</i>      | End parameter values of the surface.                                |
| <i>anext1</i>       | Start point for iteration along curve number one.                   |
| <i>enext2[]</i>     | Start parameter values of the iteration on the surface.             |
| <i>second_order</i> | if 'true' the function will attempt a second-order method directly. |

## Return values

|                |                                                            |
|----------------|------------------------------------------------------------|
| <i>cpos1</i>   | Parameter value of the curve in the intersection point.    |
| <i>gpos2[]</i> | Parameter values of the surface in the intersection point. |
| <i>dist</i>    | Distance between the points.                               |
| <i>pt_cv</i>   | The point on the curve.                                    |
| <i>pt_su</i>   | The point on the surface.                                  |

## Return values

|              |                                                      |
|--------------|------------------------------------------------------|
| <i>istat</i> | =1 Intersection. =2 Minimum value. =3 Nothing found. |
|--------------|------------------------------------------------------|

28.5.2.6 void Go::ClosestPoint::closestPtSurfSurfPlane ( const std::vector< Point > & *epoint*, const std::vector< Point > & *epnt1*, const std::vector< Point > & *epnt2*, const Point & *epar1*, const Point & *epar2*, const ParamSurface \* *psurf1*, const ParamSurface \* *psurf2*, double *aepsge*, std::vector< Point > & *gpnt1*, std::vector< Point > & *gpnt2*, Point & *gpar1*, Point & *gpar2*, int & *jstat*, AlgorithmChoice *algo* = FUNCTIONAL )

Newton iteration on the distance function between two surfaces and a plane to find a closest point or an intersection point. Ported from the sisl-function `s9iterate`.

## Parameters

|               |                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>epoint</i> | - Vector of Points containing parts of plane description. <i>epoint</i> [0] contains a point in the plane. <i>epoint</i> [1] contains the normal vector to the plane. |
| <i>epnt1</i>  | 0-2 Derivatives + normal of start point for iteration in first surface.                                                                                               |
| <i>epnt2</i>  | 0-2 Derivatives + normal of start point for iteration in second surface.                                                                                              |
| <i>epar1</i>  | Parameter pair of start point in first surface.                                                                                                                       |
| <i>epar2</i>  | Parameter pair of start point in second surface.                                                                                                                      |
| <i>psurf1</i> | Pointer to the first surface.                                                                                                                                         |
| <i>psurf2</i> | Pointer to the second surface.                                                                                                                                        |
| <i>aepsge</i> | Absolute tolerance.                                                                                                                                                   |
| <i>gpnt1</i>  | 0-2 Derivatives + normal of result of iteration in first surface.                                                                                                     |
| <i>gpnt2</i>  | 0-2 Derivatives + normal of result of iteration in second surface.                                                                                                    |
| <i>gpar1</i>  | Parameter pair of result of iteration in first surface.                                                                                                               |
| <i>gpar2</i>  | Parameter pair of result of iteration in second surface.                                                                                                              |
| <i>jstat</i>  | =1 Intersection. =2 Minimum value. =3 Nothing found.                                                                                                                  |
| <i>algo</i>   | choose whether the implementation of the algorithm should be based on general function minimization, or a geometric approach                                          |

28.5.2.7 void Go::ClosestPoint::closestPtSurfSurfPlaneFunctional ( const std::vector< Point > & *epoint*, const std::vector< Point > & *epnt1*, const std::vector< Point > & *epnt2*, const Point & *epar1*, const Point & *epar2*, const ParamSurface \* *psurf1*, const ParamSurface \* *psurf2*, double *aepsge*, std::vector< Point > & *gpnt1*, std::vector< Point > & *gpnt2*, Point & *gpar1*, Point & *gpar2*, int & *jstat* )

This is the functional-based implementation of `closestPtSurfSurfPlane`. It is called from the function above (`closestPtSurfSurfPlane()`) if it is called with `algo = FUNCTIONAL`. The user can also choose to call this function directly. The parameter description is the same as in `closestPtSurfSurfPlane()`.

28.5.2.8 void Go::ClosestPoint::closestPtSurfSurfPlaneGeometrical ( const std::vector< Point > & *epoint*, const std::vector< Point > & *epnt1*, const std::vector< Point > & *epnt2*, const Point & *epar1*, const Point & *epar2*, const ParamSurface \* *psurf1*, const ParamSurface \* *psurf2*, double *aepsge*, std::vector< Point > & *gpnt1*, std::vector< Point > & *gpnt2*, Point & *gpar1*, Point & *gpar2*, int & *jstat* )

This is the geometrically-based implementation of `closestPtSurfSurfPlane`. It is called from the function above (`closestPtSurfSurfPlane()`) if it is called with `algo = GEOMETRICAL`. The user can also choose to call this function directly. The parameter description is the same as in `closestPtSurfSurfPlane()`.

### 28.6.1 Detailed Description

Various utility functions for the compositemodel module.

### 28.6.2 Function Documentation

#### 28.6.2.1 bool Go::cmUtils::abovePlane ( Go::Point pt, Go::Point plane\_pt, Go::Point normal )

Return true if pt lies above plane as defined.

28.6.2.2 `double Go::cmUtils::ccwAngle ( Go::Point first_leg, Go::Point second_leg, Go::Point * normal = NULL )`

Return angle from first\_leg to second\_leg, in ccw direction. Dimension is 2 or 3. For dimension 3 the input normal is used to define plane. Returned angle lies in  $[0, 2\pi)$ . normal assumed to exist if dim of legs equals 3, need not be normal to legs. Only defines ccw.

28.6.2.3 `void Go::cmUtils::cwOrientation ( std::vector< Go::ftEdgeBase * > & meeting_edges, std::vector< bool > & start, double angle_tol = 1e-05 )`

Given input of edges, meeting in a common vertex (as given by start), make sure that the edges after the first element is sorted based on angle, in cw direction. In addition we also make sure that edges with common sf\_id are given in sequence. Note: Expecting that all sfs have consistent orientation (which they'll have if topology has been built)!!!

28.6.2.4 `void Go::cmUtils::cwOrientation2 ( std::vector< Go::ftEdgeBase * > & meeting_edges, std::vector< bool > & start )`

Method does not compute tangents and angles but is based on next\_, prev\_ & twin\_. We're assuming that at most two input edges are without twin.

28.6.2.5 `double Go::cmUtils::estimatedCurveLength ( ftEdgeBase * edge, int nmb_samples = 4 )`

Estimate the curve length corresponding to an edge.

28.6.2.6 `void Go::cmUtils::extendWithDegBd ( std::vector< int > & corner, std::vector< shared_ptr< Go::ParamCurve > > & bd_curves, std::vector< shared_ptr< Go::ParamCurve > > & cross_curves, int idxmin )`

Extend the set of boundary curves with degenerate curves if a degenerate surface is to be created. Handles 2 or 3 bnd\_curves.

28.6.2.7 `RectDomain Go::cmUtils::geometricParamDomain ( ParamSurface * sf )`

**Domain** of surface is rescaled according to surface lengths in geometry space.

28.6.2.8 `std::vector<std::pair<shared_ptr<Go::ParamCurve>, Go::ftFaceBase*> > Go::cmUtils::getG1FaceCurves ( Go::ftCurve & bd_curve )`

Divide the input curve into G1 segments lying on one surface only (input expected to lie on bd).

28.6.2.9 `bool Go::cmUtils::insideBdTrain ( const Go::Vector2D & sample_pt, const std::vector< Go::Vector2D > & bd_train )`

bd\_train must be a simple loop, direction may be either.

We decide whether sample\_pt lies inside polygonal domain defined by bd\_train.

- 28.6.2.10 `std::vector<int> Go::cmUtils::removeInnerCorners ( const std::vector< Go::ftEdgeBase * > & outer_loop, std::vector< int > & corners )`
- 28.6.2.11 `void Go::cmUtils::reparametrizeBdCvs ( const std::vector< shared_ptr< Go::SplineCurve > > & bd_cvs, double appr_tol, std::vector< shared_ptr< Go::SplineCurve > > & new_bd_cvs )`
- 28.6.2.12 `void Go::cmUtils::reparametrizeBdCvs2 ( const std::vector< shared_ptr< Go::SplineCurve > > & bd_cvs, double appr_tol, std::vector< shared_ptr< Go::SplineCurve > > & new_bd_cvs )`
- 28.6.2.13 `void Go::cmUtils::splitEdgesInCorners ( std::vector< shared_ptr< Go::ftEdgeBase > > & edges, const std::vector< Go::Point > & corner_pts, double gap )`

interior of an edge. To be called prior to connection with twin.

We make sure that all `corner_pts` (within gap from an edge) do not lie in the

- 28.6.2.14 `void Go::cmUtils::updateWithNewCorners ( const std::vector< Go::ftEdgeBase * > & outer_loop, std::vector< int > & corners, const std::vector< Go::Point > & add_corner_pts, double gap )`

Assuming input `corner_pts` lie inside gap of `outer_loop`, and not in the middle of a segment.

### 28.7.1 Detailed Description

This namespace contains functions used to create a Coons Patch or a Gordon Surface.

### 28.7.2 Function Documentation

**28.7.2.1** `void Go::CoonsPatchGen::addMissingCrossCurves ( const std::vector< shared_ptr< SplineCurve > > & bnd_curves, std::vector< shared_ptr< SplineCurve > > & cross_crvs )`

Generates missing cross boundary curves. In case of missing cross\_crv, we're expecting a NULL pointer. boundary\_crvs form a loop. cross\_crvs share spline space, and all cross curves point inwards = into the surface. A missing cross\_curve is indicated by a null pointer. The added cross curve will also point inwards, following parametrization given by boundary curves.

**28.7.2.2** `void Go::CoonsPatchGen::blendcoef ( double evecu[], double evecv[], double etang[], int idim, int isign, double * coef1, double * coef2 )`

Project the etang vector onto the plane defined by evecu and evecv. The projected vector will be represented as  $(*coef1)*evecu + (*coef2)*evecv$ .

#### Parameters

|              |                                           |
|--------------|-------------------------------------------|
| <i>evecu</i> | one of the vectors spanning the plane.    |
| <i>evecv</i> | one of the vectors spanning the plane.    |
| <i>etang</i> | vector to be projected.                   |
| <i>idim</i>  | the geometric dimension of the space.     |
| <i>isign</i> | sign with wich etang is to be multiplied. |
| <i>coef1</i> | scalar corresponding to evecu.            |
| <i>coef2</i> | scalar corresponding to evecv.            |

### 28.7.2.3 `SplineSurface* Go::CoonsPatchGen::createCoonsPatch ( const CurveLoop & boundary )`

Create a new [SplineSurface](#) representing the coons patch as defined by a loop of four [SplineCurves](#).

#### Parameters

|                 |                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>boundary</i> | the <a href="#">CurveLoop</a> describing the boundary of the coons patch to be generated. There must be exactly four curves, they must all be of type ' <a href="#">SplineCurve</a> ', and they must be nonrational. |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Returns

a pointer to a newly created [SplineSurface](#) representing the coons patch. The user assumes ownership of the object.

### 28.7.2.4 `SplineSurface* Go::CoonsPatchGen::createCoonsPatch ( std::vector< shared_ptr< ParamCurve > > & bd_curves, std::vector< shared_ptr< ParamCurve > > & cross_curves, double epsge, double kink_tol )`

*bd\_curves* form a loop, all *cross\_curves* point into the surface. *cross\_curves* need not fulfill twist and tangent requirements. Create a new [SplineSurface](#) representing the coons patch defined by a loop of four boundary curves, and their respective cross-tangent curves.

#### Parameters

|                     |                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------|
| <i>bd_curves</i>    | ccw loop defining the boundary of the patch, size = 4.                                                       |
| <i>cross_curves</i> | corresponding cross tangent curves, size = 4, an element may be a NULL pointer.                              |
| <i>epsge</i>        | allowed distance between corresponding end points of <i>bd_curves</i> .                                      |
| <i>kink_tol</i>     | allowed angle between end tangents of <i>bd_curves</i> and corresponding end points of <i>cross_curves</i> . |

#### Returns

pointer to the created Gordon Surface.

### 28.7.2.5 `SplineSurface* Go::CoonsPatchGen::createCoonsPatch ( std::vector< shared_ptr< SplineCurve > > & bd_curves, std::vector< shared_ptr< SplineCurve > > & cross_curves )`

Create a Gordon Surface from input curves. *bd\_curves* forms a loop, all *cross\_curves* point into the surface. Assumes curves have been preprocessed, i.e. *cross\_curves* fulfill twist and tangent requirements.

#### Parameters

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| <i>bd_curves</i>    | ccw loop defining the boundary of the patch, size = 4.                          |
| <i>cross_curves</i> | corresponding cross tangent curves, size = 4, an element may be a NULL pointer. |

#### Returns

pointer to the created Gordon Surface.

**28.7.2.6 SplineSurface\* Go::CoonsPatchGen::createGordonSurface ( std::vector< shared\_ptr< SplineCurve > > & mesh\_curves, std::vector< double > & params, int & nmb\_u\_crvs, bool use\_param\_values )**

Create a Gordon Surface from input curves and parameters. We require that both boundary curves in one direction (at least) are given. If use\_param\_values == true, we require the curves to be ordered (with parameters as given by params), with nmb\_u\_crvs u-curves up front. If use\_param\_values == false, mesh\_curves is reordered as explained in [splitMeshCurves\(\)](#) and [sortMeshCurves\(\)](#). Intersection parameters of curves are found and set in params, and nmb\_u\_crvs is also set.

#### Parameters

|                         |                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------|
| <i>mesh_curves</i>      | the iso-curves defining the Gordon Surface.                                                 |
| <i>params</i>           | the corresponding iso parameters. Updated if use_param_values == false.                     |
| <i>nmb_u_crvs</i>       | the number of curves parametrized in the u-direction. Updated if use_param_values == false. |
| <i>use_param_values</i> | whether to use the input parameters.                                                        |

#### Returns

pointer to the created Gordon Surface.

**28.7.2.7 SplineSurface\* Go::CoonsPatchGen::createGordonSurface ( std::vector< shared\_ptr< SplineCurve > > & mesh\_curves, std::vector< double > & params, int & nmb\_u\_crvs, std::vector< shared\_ptr< SplineCurve > > & cross\_curves, std::vector< int > & cross\_index, bool use\_param\_values = true )**

Create a Gordon Surface from input curves and parameters. cross\_index refers to indexing of mesh\_curves, which means that the boundary curves to which it is a tangent must be included. All cross\_curves are assumed to fulfill twist and tangent requirements.

#### Parameters

|                         |                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------|
| <i>mesh_curves</i>      | the iso-curves defining the Gordon Surface.                                                 |
| <i>params</i>           | the corresponding iso parameters. Updated if use_param_values == false.                     |
| <i>nmb_u_crvs</i>       | the number of curves parametrized in the u-direction. Updated if use_param_values == false. |
| <i>cross_curves</i>     | cross tangent curves for the Gordon Surface, corresponding to element in mesh_curves.       |
| <i>cross_index</i>      | referring to index element in mesh_curves.                                                  |
| <i>use_param_values</i> | whether to use the input parameters.                                                        |

#### Returns

pointer to the created Gordon Surface.

**28.7.2.8 SplineSurface\* Go::CoonsPatchGen::doCreateSurface ( std::vector< shared\_ptr< SplineCurve > > & mesh\_curves, std::vector< double > & params, int & nmb\_u\_crvs, std::vector< shared\_ptr< SplineCurve > > & cross\_curves, std::vector< int > & cross\_index )**

Create a Gordon Surface interpolating the input curves in the input parameters. mesh\_curves assumed to be ordered (i.e. u-curves first, with ascending parameter values), and missing boundary curve(s) in at most one direction. Expecting end conditions are satisfied.

## Parameters

|                     |                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------|
| <i>mesh_curves</i>  | iso-curves for Gordon Surface.                                                                        |
| <i>params</i>       | iso-parameters for the mesh_curves.                                                                   |
| <i>nmb_u_crvs</i>   | the number of curves parametrized in the u-direction. May alter as the parameter directions may swap. |
| <i>cross_curves</i> | the cross tangent curves along iso-curves for the Gordon Surface.                                     |
| <i>cross_index</i>  | index in mesh_curves of corresponding boundary curve.                                                 |

## Returns

pointer to the created Gordon Surface.

**28.7.2.9** void Go::CoonsPatchGen::fixCrossEndPts ( const std::vector< shared\_ptr< SplineCurve > > & *bd\_curves*, const std::vector< shared\_ptr< SplineCurve > > & *cross\_curves* )

Make sure that the end points of the existing cross\_tangent\_curves match the end derivatives of the corresponding bd\_curves. Curves are oriented CCW.

## Parameters

|                     |                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>bd_curves</i>    | curves along the boundary, ccw orientated. Will not be altered.                                                          |
| <i>cross_curves</i> | the corresponding cross tangent curves (same orientation). The curve objects referred to by the pointers may be altered. |

**28.7.2.10** void Go::CoonsPatchGen::getCrossTangs ( const std::vector< shared\_ptr< SplineCurve > > & *curves*, std::vector< shared\_ptr< SplineCurve > > & *mod\_cross\_curves*, double *tol1*, double *tol2* )

Prepare cross tangents for surface creation. curves contains boundary\_curve, cross\_curve; one edge at a time (iedge\*2 curves). boundary curves form a loop. All curves share spline space, and all cross curves point inwards = into the surface. A missing cross\_curve is indicated by a null pointer. Output mod\_cross\_curves fulfills tangent and twist conditions.

**28.7.2.11** void Go::CoonsPatchGen::getTangBlends ( std::vector< shared\_ptr< SplineCurve > > & *curves*, int *iedge*, std::vector< shared\_ptr< SplineCurve > > & *blend\_functions* )

Find blending functions used to blend two derivative along some boundary curves corresponding to a surface, into a cross derivative curve pr edge. Get curves for blending of two tangent curves into one cross tangent curve. Size of curves = iedge \* 3 (i.e. bd\_curve, cross\_curve, tangent curve). Boundary curves form a loop, and all curves share orientation and line space. cross-curves point inwards.

**28.7.2.12** void Go::CoonsPatchGen::hermit ( double *econd*[], int *icond*, bool *hasder1*, double *astart*, double *aend*, int *idim* )

Hermite interpolate the input points.

## Parameters

|                |                                                                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>econd</i>   | array containing the points and derivatives to be interpolated. The ordering is <start_pt, (start_tan,) end_der, end_pt> The array will contain the coefficients of the spline curve fulfilling the input requirements. |
| <i>icond</i>   | number of interpolation conditions.                                                                                                                                                                                     |
| <i>hasder1</i> | Whether derivative is given in the start of the interval                                                                                                                                                                |
| <i>astart</i>  | start parameter of the produced curve.                                                                                                                                                                                  |
| <i>aend</i>    | end parameter of the produced curve.                                                                                                                                                                                    |
| <i>idim</i>    | dimension of the geometric space.                                                                                                                                                                                       |

28.7.2.13 **SplineSurface\*** `Go::CoonsPatchGen::loftSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, int nmb_crvs )`

Create a lofting surface based on the input curves.

## Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface. |
| <i>nmb_crvs</i>    | the number of curves referred to by first_curve.   |

## Returns

pointer to the created lofting surface.

28.7.2.14 **SplineSurface\*** `Go::CoonsPatchGen::loftSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, std::vector< double >::iterator first_param, int nmb_crvs )`

Create a lofting surface interpolating the input curves in the input parameters.

## Parameters

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface.               |
| <i>first_param</i> | iso parameter to corresponding curve referred to by first_curve. |
| <i>nmb_crvs</i>    | the number of curves referred to by first_curve.                 |

## Returns

pointer to the created lofting surface.

28.7.2.15 **SplineSurface\*** `Go::CoonsPatchGen::loftSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, std::vector< double >::iterator first_param, int nmb_crvs, std::vector< shared_ptr< SplineCurve > >::iterator first_cross_curve, std::vector< int > & cross_index )`

Create a lofting surface interpolating the input curves and cross tangent curves in the input parameters. All curves assumed to share spline space.

## Parameters

|                          |                                                                          |
|--------------------------|--------------------------------------------------------------------------|
| <i>first_curve</i>       | iterator to first iso-curve in the lofted surface.                       |
| <i>first_param</i>       | iso parameter to corresponding curve referred to by <i>first_curve</i> . |
| <i>nmb_crvs</i>          | the number of curves referred to by <i>first_curve</i> .                 |
| <i>first_cross_curve</i> | iterator to first cross tangent curve in the lofted surface.             |
| <i>cross_index</i>       | referring to index of corresponding boundary curve.                      |

## Returns

pointer to the created lofting surface.

```
28.7.2.16 void Go::CoonsPatchGen::makeLoftParams (std::vector< shared_ptr< SplineCurve > >::const_iterator
 first_curve, int nmb_crvs, double param_length, std::vector< double > & params)
```

Calculate iso parameters for the input curves. The curves are expected to be ordered, i.e. corresponding to increasing iso parameters. Curves are given iso-parameters in the range 0.0 to *param\_length*.

## Parameters

|                     |                                                   |
|---------------------|---------------------------------------------------|
| <i>first_curve</i>  | iterator to first iso curve.                      |
| <i>nmb_crvs</i>     | the number of input curves.                       |
| <i>param_length</i> | length of parameter domain.                       |
| <i>params</i>       | the computed iso parameters for the input curves. |

```
28.7.2.17 void Go::CoonsPatchGen::reparamBoundaryCurve (std::vector< shared_ptr< SplineCurve > > & curves,
 double aconst)
```

Check length of tangent vectors at the endpoints of a curve compared to the size of the curve. If the vectors are too long, reparametrize the curve and all the other curves in vector. All curves expected to share parametrization. First curve is a bnd curve. Optional additional curves may be cross tangent curve. Function reparametrizes bnd curve so that end tangents have length equal to *aconst*. Typical value is 1/3 of edge-length.

## Parameters

|               |                                     |
|---------------|-------------------------------------|
| <i>curves</i> | input and output curves.            |
| <i>aconst</i> | scalar defining end tangent length. |

```
28.7.2.18 void Go::CoonsPatchGen::sortMeshCurves (std::vector< shared_ptr< SplineCurve > > & mesh_curves,
 std::vector< double > & params, int nmb_u_crvs, std::vector< int > & cross_index)
```

Given that *mesh\_curves* has been regrouped with u-curves up front, we sort the vector according to values in *params*.

28.7.2.19 void Go::CoonsPatchGen::splitMeshCurves ( std::vector< shared\_ptr< SplineCurve > > & mesh\_curves, std::vector< double > & params, int & nmb\_u\_crvs, std::vector< int > & cross\_index, double epsgeo )

Given input iso-curves, the curves are analyzed and the ordering altered such that the nmb\_u\_crvs first elements are u-curves, and the rest are v-curves. Calculated iso parameter for the curves is returned in params.

#### Parameters

|             |                                                                   |
|-------------|-------------------------------------------------------------------|
| mesh_curves | iso-curves for a surface, sorted inside function.                 |
| params      | calculated parameters for the iso-curves.                         |
| nmb_u_crvs  | the number of curves parametrized in the u-direction.             |
| cross_index | elements referring to mesh_curves, updated inside function.       |
| epsgeo      | geometrical tolerance defining intersections between mesh_curves. |

28.7.2.20 SplineSurface\* Go::CoonsPatchGen::tpSurface ( const std::vector< shared\_ptr< SplineCurve > > & mesh\_curves, std::vector< double > params, int nmb\_u\_crvs, const std::vector< shared\_ptr< SplineCurve > > & cross\_curves, std::vector< int > & cross\_index )

Make tensor product surface which interpolates given grid points. All curves assumed to share spline space.

#### Parameters

|              |                                                                        |
|--------------|------------------------------------------------------------------------|
| mesh_curves  | curves to be interpolated in the Gordon Surface, both u- and v-curves. |
| params       | the iso parameters for the curves.                                     |
| nmb_u_crvs   | the number of curves parametrized in the u-direction.                  |
| cross_curves | cross tangent curves for the Gordon Surface.                           |
| cross_index  | referring to index of corresponding boundary curve.                    |

#### Returns

pointer the created lofting surface.

## 28.8 Go::CoonsPatchVolumeGen Namespace Reference

This namespace contains functions used to create a Coons Patch volume.

### Functions

- void [get\\_corners](#) (shared\_ptr< Go::SplineSurface > surf, std::vector< Go::Point > &pts)  
*Used internally in the geometry construction.*
- void [push\\_corners](#) (std::vector< Go::Point > &pts\_to, const std::vector< Go::Point > pts\_from, int pos0, int pos1, int pos2, int pos3)  
*Used internally in the geometry construction.*
- bool [edge\\_curves\\_equal](#) (shared\_ptr< Go::SplineSurface > sf1, double par1, bool is\_u\_dir1, shared\_ptr< Go::SplineSurface > sf2, double par2, bool is\_u\_dir2, double tol)  
*Used internally in the geometry construction.*

- [SplineVolume](#) \* `createCoonsPatchDirectly` (const [Go::SplineSurface](#) \*surf\_u\_min, const [Go::SplineSurface](#) \*surf\_u\_max, const [Go::SplineSurface](#) \*surf\_v\_min, const [Go::SplineSurface](#) \*surf\_v\_max, const [Go::SplineSurface](#) \*surf\_w\_min, const [Go::SplineSurface](#) \*surf\_w\_max)
- [SplineVolume](#) \* `createCoonsPatch` (const [Go::SplineSurface](#) \*surf\_u\_min, const [Go::SplineSurface](#) \*surf\_u\_max, const [Go::SplineSurface](#) \*surf\_v\_min, const [Go::SplineSurface](#) \*surf\_v\_max, const [Go::SplineSurface](#) \*surf\_w\_min, const [Go::SplineSurface](#) \*surf\_w\_max, double tol=1.0e-05)

### 28.8.1 Detailed Description

This namespace contains functions used to create a Coons Patch volume.

### 28.8.2 Function Documentation

**28.8.2.1** `SplineVolume* Go::CoonsPatchVolumeGen::createCoonsPatch ( const Go::SplineSurface * surf_u_min, const Go::SplineSurface * surf_u_max, const Go::SplineSurface * surf_v_min, const Go::SplineSurface * surf_v_max, const Go::SplineSurface * surf_w_min, const Go::SplineSurface * surf_w_max, double tol = 1.0e-05 )`

Create a new [SplineVolume](#) representing the coons patch of six [SplineSurfaces](#), the six faces of the volume. We test if the faces are non-rational, lie in the same space, and have coinciding edge curves where needed. The B-spline bases of the surfaces might be reversed, swapped, have order raised, knots inserted and parameter interval rescaled to [0,1], in order to be able to use `createCoonsPatchDirectly()`

#### Parameters

|                         |                                                     |
|-------------------------|-----------------------------------------------------|
| <code>surf_u_min</code> | One of faces/isosurfaces for the u-direction        |
| <code>surf_u_max</code> | The other faces/isosurfaces for the u-direction     |
| <code>surf_v_min</code> | One of faces/isosurfaces for the v-direction        |
| <code>surf_v_max</code> | The other faces/isosurfaces for the v-direction     |
| <code>surf_w_min</code> | One of faces/isosurfaces for the w-direction        |
| <code>surf_w_max</code> | The other faces/isosurfaces for the w-direction     |
| <code>tol</code>        | Tolerance when identifying equal curves and corners |

#### Returns

a pointer to a newly created [SplineVolume](#) representing the coons patch. The user assumes ownership of the object

**28.8.2.2** `SplineVolume* Go::CoonsPatchVolumeGen::createCoonsPatchDirectly ( const Go::SplineSurface * surf_u_min, const Go::SplineSurface * surf_u_max, const Go::SplineSurface * surf_v_min, const Go::SplineSurface * surf_v_max, const Go::SplineSurface * surf_w_min, const Go::SplineSurface * surf_w_max )`

Create a new [SplineVolume](#) representing the coons patch of six [SplineSurfaces](#), the six faces of the volume. Here we assume that the faces are non-rational and lie in the same space, and all have the same B-spline basis (knot vectors and degrees are the same) along coinciding sides, i.e. for two surfaces with a common side, the two coinciding edge curves have the same B-spline basis. Also, all B-spline bases are assumed to have knot interval [0.0, 1.0].

## Parameters

|                   |                                 |
|-------------------|---------------------------------|
| <i>surf_u_min</i> | The face/isosurface for u = 0.0 |
| <i>surf_u_max</i> | The face/isosurface for u = 1.0 |
| <i>surf_v_min</i> | The face/isosurface for v = 0.0 |
| <i>surf_v_max</i> | The face/isosurface for v = 1.0 |
| <i>surf_w_min</i> | The face/isosurface for w = 0.0 |
| <i>surf_w_max</i> | The face/isosurface for u = 1.0 |

## Returns

a pointer to a newly created [SplineVolume](#) representing the coons patch. The user assumes ownership of the object.

**28.8.2.3** `bool Go::CoonsPatchVolumeGen::edge_curves_equal ( shared_ptr< Go::SplineSurface > sf1, double par1, bool is_u_dir1, shared_ptr< Go::SplineSurface > sf2, double par2, bool is_u_dir2, double tol )`

Used internally in the geometry construction.

**28.8.2.4** `void Go::CoonsPatchVolumeGen::get_corners ( shared_ptr< Go::SplineSurface > surf, std::vector< Go::Point > & pts )`

Used internally in the geometry construction.

**28.8.2.5** `void Go::CoonsPatchVolumeGen::push_corners ( std::vector< Go::Point > & pts_to, const std::vector< Go::Point > pts_from, int pos0, int pos1, int pos2, int pos3 )`

Used internally in the geometry construction.

## 28.9 Go::CreatorsUtils Namespace Reference

Related to the generation of cross tangent curves.

## 28.9.1 Detailed Description

Related to the generation of cross tangent curves.

## 28.9.2 Function Documentation

28.9.2.1 `shared_ptr<Go::SplineCurve> GO_API Go::CreatorsUtils::createCrossTangent ( const Go::CurveOnSurface & cv )`

Generate the inwards pointing cross-tangent curve along the input trim curve.

### Parameters

|                 |                 |
|-----------------|-----------------|
| <code>cv</code> | the trim curve. |
|-----------------|-----------------|

### Returns

the inwards cross tangent curve.

28.9.2.2 `shared_ptr<Go::SplineCurve> GO_API Go::CreatorsUtils::createCrossTangent ( const Go::CurveOnSurface & cv, shared_ptr< Go::SplineCurve > basis_space_cv, const Go::SplineCurve * cross_cv_ref, bool appr_offset_cv = true )`

The cross tangent cv along input cv is created. Length given by length of derivs in sf along cv or by input\_cross\_cv if it exists. Direction of created cross tangent cv is to the left of cv (i.e. it should point into the surface). If input\_cross\_cv exists so does basis\_space\_cv and they must share parametrization. If input\_cross\_cv exists, but not basis\_space\_cv, it shares parametrization with cv.

### Parameters

|                             |                                                                                                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cv</code>             | the trim curve along which we are to compute the cross tangent cv.                                                                                                    |
| <code>basis_space_cv</code> | if != NULL we use the basis and parametrization of basis_space_cv.                                                                                                    |
| <code>cross_cv_ref</code>   | if != NULL the curve defines the angle between the boundary curve and the new cross tangent curve. Additionally it defines the length of the new cross tangent curve. |
| <code>appr_offset_cv</code> | whether the method should approximate the offset curve (as opposed to the cross tangent curve).                                                                       |

### Returns

the cross tangent (or offset) curve.

28.9.2.3 `void GO_API Go::CreatorsUtils::fixSeemCurves ( shared_ptr< BoundedSurface > bd_sf, std::vector< shared_ptr< CurveOnSurface > > & loop_cvs, bool closed_dir_u, bool closed_dir_v, double tol )`

Repair erranous seem curves in bounded surfaces with closed underlying surfaces

28.9.2.4 `void GO_API Go::CreatorsUtils::fixTrimCurves ( shared_ptr< Go::BoundedSurface > bd_sf, double epsgeo_frac = 1.0, double tol = 1.0e-3, double tol2 = 1.0e-2, double ang_tol = 1.0e-2 )`

Repair errantous trimming curves in bounded surfaces and compute missing parameter curves in the corresponding [CurveOnSurface](#) curves

28.9.2.5 `SplineCurve GO_API* Go::CreatorsUtils::getParametricCurve ( const std::vector< shared_ptr< const CurveOnSurface > > & cv )`

Helper function. Returns the parametric representation of the input curve. The returned curve is created (i.e. it should be handled by a smart ptr)! This function takes as argument a vector of (shared pointers to) [CurveOnSurfaces](#), which are assumed to lie on the same surface and to represent consecutive parts of a larger curve, and return the parametric representation of this larger curve.

#### Parameters

|           |                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cv</i> | a vector of (shared pointers to) <a href="#">CurveOnSurfaces</a> . We suppose that these curves are all lying on the same surface and that they constitute consecutive parts of a global curve. |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Returns

if successful, a pointer to the newly generated [SplineCurve](#), which represents the global curve that is the union of the input curves. This [SplineCurve](#) is represented in the parameter plane of the surface, and is therefore a 2D curve. If it could not be constructed (due a failure of any of the provided [CurveOnSurfaces](#) to provide their internal parameter curve), a null pointer is returned instead. The user assumes ownership of the [SplineCurve](#).

28.9.2.6 `shared_ptr<Go::Point> Go::CreatorsUtils::projectCurvePoint ( const ParamSurface * sf, bool closed_dir_u, bool closed_dir_v, const Go::ParamCurve * space_cv, double cv_par, double epsgeo = 1e-04 )`

28.9.2.7 `shared_ptr<Go::Point> Go::CreatorsUtils::projectCurvePoint ( const SplineSurface & sf, bool closed_dir_u, bool closed_dir_v, const Go::ParamCurve * space_cv, double cv_par, double epsgeo = 1e-04 )`

Project a point on a space curve onto a surface. If the surface is closed, and the curve follows the seam at the point in question, then the point corresponding to a counterclockwise curve is chosen. If the programmer knows that this is not the case, then this must be handled.

#### Parameters

|                     |                                                                                       |
|---------------------|---------------------------------------------------------------------------------------|
| <i>sf</i>           | the surface the point is projected onto                                               |
| <i>closed_dir_u</i> | boolean that is <code>true</code> if the surface is closed in the <i>u</i> -direction |
| <i>closed_dir_v</i> | boolean that is <code>true</code> if the surface is closed in the <i>v</i> -direction |
| <i>space_cv</i>     | the curve to be projected                                                             |
| <i>cv_par</i>       | the parameter of the curve point to be projected                                      |

#### Returns

the projected point in the form of a parameter pair

28.9.2.8 `std::vector<Go::Point> GO_API Go::CreatorsUtils::projectPoint ( const Go::ParamSurface * sf, bool closed_dir_u, bool closed_dir_v, const Go::Point & space_pt, double epsgeo = 1e-04 )`

Project a point in space onto a surface. If the surface is closed, and the point is on the seam, then the set of possible candidates is returned.

#### Parameters

|                                        |                                                                                       |
|----------------------------------------|---------------------------------------------------------------------------------------|
| <i>sf</i>                              | the surface the point is projected onto                                               |
| <i>closed_dir</i> <sub>↔<i>u</i></sub> | boolean that is <code>true</code> if the surface is closed in the <i>u</i> -direction |
| <i>closed_dir</i> <sub>↔<i>v</i></sub> | boolean that is <code>true</code> if the surface is closed in the <i>v</i> -direction |
| <i>space_pt</i>                        | the point to be projected                                                             |

#### Returns

vector of candidates of projected points in the form of parameter pairs

## 28.10 Go::Curvature Namespace Reference

[Curvature](#) analysis related to curves.

### Functions

- void [curvatureRadiusPoints](#) (const [SplineCurve](#) &*curve*, double *curveRad*, std::vector< double > &*pos*)
- void [minimalCurvatureRadius](#) (const [SplineCurve](#) &*curve*, double &*mincurv*, double &*pos*)

### 28.11.1 Detailed Description

[Curvature](#) analysis related to surfaces. Functions computing fundamental forms and curvature.

### 28.11.2 Function Documentation

28.11.2.1 void `Go::CurvatureAnalysis::computeFirstFundamentalForm` ( const ParamSurface &sf, double u, double v, int derivs, std::vector< double > &form )

Computes the coefficients of the first fundamental form. The returned values are stored { E F G [Eu Fu Gu Ev Fv Gv [Euu Fuu Guu Euv Fuv Guv Evv Fvv Gvv [...]] ]. Only one derivative is implemented so far.

#### Parameters

|               |                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sf</i>     | reference to the concerned surface                                                                                                                                                 |
| <i>u</i>      | first parameter of point where we want to compute the first fundamental form                                                                                                       |
| <i>v</i>      | second parameter of point where we want to compute the first fundamental form                                                                                                      |
| <i>derivs</i> | number of (partial) derivatives of the first fundamental form that we want to include in the result. So far, only the computation of the first derivative is actually implemented. |
| <i>form</i>   | the computed values, on the format described above                                                                                                                                 |

28.11.2.2 void `Go::CurvatureAnalysis::computeSecondFundamentalForm` ( const ParamSurface &sf, double u, double v, double form1[3], double form2[3] )

Computes the coefficients of the first and second fundamental forms. The returned values are stored { E F G } in form1 and { e f g } in form2. This function cannot compute derivatives.

#### Parameters

|           |                                    |
|-----------|------------------------------------|
| <i>sf</i> | reference to the concerned surface |
|-----------|------------------------------------|

## Parameters

|              |                                                                               |
|--------------|-------------------------------------------------------------------------------|
| <i>u</i>     | first parameter of point where we want to compute the fundamental forms.      |
| <i>v</i>     | second parameter of point where we want to compute the fundamental forms      |
| <i>form1</i> | the values associated with the first fundamental form will be returned here.  |
| <i>form2</i> | the values associated with the second fundamental form will be returned here. |

28.11.2.3 void Go::CurvatureAnalysis::curvatures ( const ParamSurface & *sf*, double *u*, double *v*, double & *K*, double & *H* )

Computes the Gaussian (K) and mean (H) curvatures.

## Parameters

|           |                                                                   |
|-----------|-------------------------------------------------------------------|
| <i>sf</i> | reference to the concerned surface                                |
| <i>u</i>  | first parameter of point where we want to carry out computation   |
| <i>v</i>  | second parameter of point where weh want to carry out computation |
| <i>K</i>  | value of Gaussian curvature returned here                         |
| <i>H</i>  | value of mean curvature returned here                             |

28.11.2.4 void Go::CurvatureAnalysis::evaluateMinCurvatureRadius ( const ParamSurface & *sf*, double *start\_u*, double *end\_u*, double *start\_v*, double *end\_v*, double *tolerance*, std::vector< double > & *param\_u*, std::vector< double > & *param\_v*, std::vector< std::vector< double > > & *curvs*, double & *mincurv*, double & *minpos\_u*, double & *minpos\_v*, bool *initialize* )

Estimate the minium curvature radius of the surface *sf* in the parameter domain [*start\_u*,*end\_u*]x[*start\_v*,*end\_v*] by evaluating the curvature radius in a grid and fetch the smallest one. The grid density is computed from the given tolerance

28.11.2.5 void Go::CurvatureAnalysis::minimalCurvatureRadius ( const ParamSurface & *sf*, double *tolerance*, double & *mincurv*, double & *pos\_u*, double & *pos\_v*, double *degenerate\_eps*, double *curv\_tol* = 1.0e-3 )

Estimate the minimum curvature radius of the surface *sf*.

## Parameters

|                       |                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------|
| <i>sf</i>             | the given surface                                                                              |
| <i>tolerance</i>      | influences the density of the search                                                           |
| <i>mincurve</i>       | the computed minimum curvature radius                                                          |
| <i>pos_u</i>          | parameter in the first parameter direction corresponding to the minimum curvature radius       |
| <i>pos_v</i>          | parameter in the second parameter direction corresponding to the minimum curvature radius      |
| <i>degenerate_eps</i> | maximum length of a degenenerate boundary, used to check whether special treatment is required |
| <i>curv_tol</i>       | default parameter used to limit the search                                                     |

28.11.2.6 void Go::CurvatureAnalysis::principalCurvatures ( const ParamSurface & sf, double u, double v, double & k1, Point & d1, double & k2, Point & d2 )

Computes the principal curvatures of a surface, sf, in the parameter value (u,v) along with the corresponding parameter directions.

### 28.12.1 Detailed Description

Various functions for generating SplineCurve s by approximation, blending, etc.

### 28.12.2 Function Documentation

28.12.2.1 SplineCurve GO\_API \* Go::CurveCreators::approxCurves ( shared\_ptr< ParamCurve > \* first\_crv, shared\_ptr< ParamCurve > \* last\_crv, const std::vector< Point > & start\_pt, const std::vector< Point > & end\_pt, double approx\_tol, double & maxdist, int max\_iter = 5, int degree = 3 )

Given input curves, we approximate with one cubic spline curve, fulfilling end requirements. This function is used generate one SplineCurve which approximates a sequence of (supposedly end-to-end continuous) input SplineCurves. In addition, the user can define explicitly the start and end point and tangent of the generated curve.

## Parameters

|                  |                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>first_crv</i> | pointer to the start of a range of (shared pointers to) SplineCurves, supposedly stored so that the end point of each curve coincides with the start point of the succeeding one.                               |
| <i>last_crv</i>  | pointer to one-past-last of the range of SplineCurves.                                                                                                                                                          |
| <i>start_pt</i>  | The user can choose to explicitly specify the start point and tangent of the curve to be generated. If so, then this vector must contain one or two elements: the start point and optionally the start tangent. |
| <i>end_pt</i>    | The user can choose to explicitly specify the end point and tangent of the curve to be generated. If so, then this vector must contain one or two elements: the end point and optionally the end tangent.       |
| <i>approxtol</i> | The routine will try to generate a curve that fits the given curves within a tolerance of 'approxtol', but is not guaranteed to succeed. If unsuccessful, a message will be written to standard output.         |
| <i>maxdist</i>   | Reports the maximum found distance between the generated curve and the input curves.                                                                                                                            |

## Return values

|                 |                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------|
| <i>max_iter</i> | Specify the maximum number of iterations that is allowed in order to converge to a solution. |
|-----------------|----------------------------------------------------------------------------------------------|

## Returns

a raw pointer to the generated [SplineCurve](#). User assumes ownership.

### 28.12.2.2 SplineCurve GO\_API\* Go::CurveCreators::blend ( const SplineCurve & *alpha\_1*, const SplineCurve & *f\_1*, const SplineCurve & *alpha\_2*, const SplineCurve & *f\_2* )

Given blend functions *alpha\_1* & *alpha\_2* (represented as 1-dimensional SplineCurves), and the spline curves *f\_1* and *f\_2*, return the blended expression ' $\alpha_1 * f_1 + \alpha_2 * f_2$ '. **NB:** All the curves given as input must be defined on the same parameter interval. Their knotvectors and orders do not have to be equal, though.

## Parameters

|                |                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>alpha_1</i> | the multiplier function for the first curve, ' <i>f_1</i> '. It is represented as an 1-dimensional <a href="#">SplineCurve</a> .  |
| <i>f_1</i>     | The first <a href="#">SplineCurve</a> to be blended.                                                                              |
| <i>alpha_2</i> | the multiplier function for the second curve, ' <i>f_2</i> '. It is represented as an 1-dimensional <a href="#">SplineCurve</a> . |
| <i>f_2</i>     | The second <a href="#">SplineCurve</a> to be blended.                                                                             |

## Returns

A raw pointer to the newly generated [SplineCurve](#), a blend between '*f\_1*' and '*f\_2*'. The user assumes ownership.

### 28.12.2.3 SplineCurve GO\_API\* Go::CurveCreators::createCircle ( Point *center*, Point *axis*, Point *normal*, double *radius* )

Create a circle.

Generate a 3D [SplineCurve](#) representing a circle. Assuming dimension is 3.

## Parameters

|               |                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------|
| <i>center</i> | the center point of the circle,                                                                      |
| <i>axis</i>   | a vector pointing from the center point of the circle and towards start and end point of the circle. |
| <i>normal</i> | the normal to the plane in which the circle lie.                                                     |
| <i>radius</i> | the radius of the circle to generate.                                                                |

## Returns

a raw pointer to the generated [SplineCurve](#), representing the specified circle. User assumes ownership.

**28.12.2.4** `std::vector<shared_ptr<SplineCurve>> Go::CurveCreators::curveApprox ( shared_ptr< ParamCurve > cvs[], int nmb_cvs, const BsplineBasis & init_basis, double tol )`

Approximate a number of curves in the same spline space given an initial spline space that may be refined. The approximation tolerance is tol

**28.12.2.5** `std::vector<shared_ptr<SplineCurve>> Go::CurveCreators::curveApprox ( shared_ptr< ParamCurve > cvs[], int nmb_cvs, double tol, double degree = 3 )`

Approximate a number of curves in the same spline space. The approximation tolerance is tol

**28.12.2.6** `shared_ptr<Go::SplineCurve> GO_API Go::CurveCreators::insertParamDomain ( const Go::SplineCurve & cv_1d, double knot_tol = 1e-08 )`

Given input of 1-dimensional curve, return the 2-dimensional visualization (x, f(x)).

**28.12.2.7** `SplineCurve GO_API* Go::CurveCreators::liftParameterCurve ( shared_ptr< ParamCurve > & parameter_cv, shared_ptr< ParamSurface > & surf, double epsge )`

Lift the parameter\_cv onto surf.

'Lift' a 2D parameter curve onto a surface. (This means generate a space curve lying on the surface, defined as the curved obtained when evaluating the surface at the parameter points given by the 2D curve).

## Parameters

|                     |                                                                                          |
|---------------------|------------------------------------------------------------------------------------------|
| <i>parameter_cv</i> | the 2D parameter curve. Its values should be kept within the parameter domain of 'surf'. |
| <i>surf</i>         | the surface on which the obtained 3D curve will lie.                                     |
| <i>epsge</i>        | geometrical tolerance used when generating the curve                                     |

## Returns

a raw pointer to the generated spatial [SplineCurve](#). User assumes ownership.

### 28.12.2.8 SplineCurve GO\_API\* Go::CurveCreators::multCurveWithFunction ( const SplineCurve & *alpha*, const SplineCurve & *f* )

Given a spline curve *f\_i* on a space of dimension *n*, and a (1-dim) spline function *alpha\_i* (not necessarily a Bezier curve) defined on the same space, return the product. Construct a [SplineCurve](#) which is the 'product' of another [SplineCurve](#) and a function (which is given as a 1-dimensional [SplineCurve](#)). **NB:** The two [SplineCurves](#) given as argument must be defined on exactly the same parameter interval. Their knotvectors and orders do not have to be equal, though.

#### Parameters

|              |                                                                                    |
|--------------|------------------------------------------------------------------------------------|
| <i>alpha</i> | the multiplier function, given here as a 1-dimensional <a href="#">SplineCurve</a> |
| <i>f</i>     | the <a href="#">SplineCurve</a> to be multiplied with                              |

#### Returns

A raw pointer to the newly generated [SplineCurve](#), a product between '*f*' and the '*alpha*' function. The user assumes ownership.

### 28.12.2.9 SplineCurve GO\_API\* Go::CurveCreators::offsetCurve ( const SplineCurve & *cv*, Point *offset\_val* )

Return the spline curve given by  $cv(t) + offset\_val$ .

### 28.12.2.10 void Go::CurveCreators::projectCurve ( shared\_ptr< ParamCurve > & *space\_cv*, shared\_ptr< ParamSurface > & *surf*, double *epsge*, shared\_ptr< SplineCurve > & *proj\_cv*, shared\_ptr< SplineCurve > & *par\_cv* )

### 28.12.2.11 SplineCurve GO\_API\* Go::CurveCreators::projectSpaceCurve ( shared\_ptr< ParamCurve > & *space\_cv*, shared\_ptr< ParamSurface > & *surf*, shared\_ptr< Point > & *start\_par\_pt*, shared\_ptr< Point > & *end\_par\_pt*, double *epsge*, const RectDomain \* *domain\_of\_interest* = NULL )

Project the *space\_cv* into parameter domain given by *surf*. *start\_par\_pt* (& *end\*\_* not needed, but useful to ensure correct evaluation). Generate a [SplineCurve](#) which lies on a given (part of a) [SplineSurface](#) and is the projection of a given [SplineCurve](#) onto that surface.

#### Parameters

|                           |                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>space_cv</i>           | the <a href="#">SplineCurve</a> (in 3D space) that we want to project onto the surface.                                                                                                                                                                 |
| <i>surf</i>               | The surface we will project the curve onto. The resulting curve will therefore lie in this surface.                                                                                                                                                     |
| <i>start_par_pt</i>       | if the user wants to explicitly define where the start point of the curve should lie, ' <i>start_par_pt</i> ' could be set to point to this point. It can also be a zero pointer, in which case the start point is determined just like any other point |
| <i>end_par_pt</i>         | if the user wants to explicitly define where the end point of the curve should lie, ' <i>end_par_pt</i> ' could be set to point to this point. It can also be a zero pointer, in which case the end point is determined just like any other point.      |
| <i>epsge</i>              | The geometrical tolerance to use when generating the projected curve. Max dist in surface from exact projection.                                                                                                                                        |
| <i>domain_of_interest</i> | If the user do not want a projection onto the whole ' <i>surf</i> ', he/she can specify the part of the surface to use by limiting the parametric domain to use. If this pointer is left as a null pointer, the whole surface is used.                  |

**Returns**

a raw pointer to the generated [SplineCurve](#). User assumes ownership.

**28.13 Go::CurveInterpolator Namespace Reference**

Curve interpolation functionality not adapted to the [Interpolator](#) class.

**Functions**

- [SplineCurve](#) \* [regularInterpolation](#) ([const BsplineBasis](#) &basis, [std::vector< double >](#) &par, [std::vector< double >](#) &points, [int](#) dimension, [bool](#) rational, [std::vector< double >](#) &weights)

**28.13.1 Detailed Description**

Curve interpolation functionality not adapted to the [Interpolator](#) class.

**28.13.2 Function Documentation**

**28.13.2.1** [SplineCurve\\*](#) [Go::CurveInterpolator::regularInterpolation](#) ( [const BsplineBasis](#) & *basis*, [std::vector< double >](#) & *par*, [std::vector< double >](#) & *points*, [int](#) *dimension*, [bool](#) *rational*, [std::vector< double >](#) & *weights* )

Interpolate a set of regular, parameterized interpolation points. The parameterization is assumed to correspond to the given B-spline basis (select interpolation points in the Greville points). The function throws if the input parameters are inconsistent

**28.14 Go::FaceUtilities Namespace Reference****Functions**

- void [getBoundaryData](#) ([ftSurface](#) \*face, [int](#) nmb\_sample, [std::vector< SamplePointData >](#) &sample\_points)
- void [getInnerData](#) ([ftSurface](#) \*face, [int](#) nmb\_sample\_u, [int](#) nmb\_sample\_v, [std::vector< SamplePointData >](#) &sample\_points)

- [bool](#) [enforceVxCoLinearity](#) ([shared\\_ptr< Vertex >](#) vx, [double](#) tol, [double](#) ang\_tol)

**28.14.1 Detailed Description**

Utility functionality for faces in order to release the need for private functions in [ftSurface](#)

## 28.14.2 Function Documentation

28.14.2.1 `bool Go::FaceUtilities::enforceCoLinearity ( ftSurface * face1, ftEdge * edge1, ftSurface * face2, double tol, double ang_tol )`

Enforce colinearity of coefficients of spline surfaces related to the given faces Return value = false : No modification

28.14.2.2 `bool Go::FaceUtilities::enforceVxCoLinearity ( shared_ptr< Vertex > vx, double tol, double ang_tol )`

28.14.2.3 `void Go::FaceUtilities::getBoundaryData ( ftSurface * face, int nmb_sample, std::vector< SamplePointData > & sample_points )`

28.14.2.4 `void Go::FaceUtilities::getInnerData ( ftSurface * face, int nmb_sample_u, int nmb_sample_v, std::vector< SamplePointData > & sample_points )`

## 28.15 Go::ftVolumeTools Namespace Reference

This namespace contains service functions related to [ftVolume](#).

### Functions

- `std::vector< shared_ptr< ftVolume > > splitVolumes (shared_ptr< ftVolume > &vol1, shared_ptr< ftVolume > &vol2, double eps, std::vector< int > &config)`
- `std::vector< shared_ptr< ftVolume > > splitVolumes (shared_ptr< ftVolume > &vol, shared_ptr< ftSurface > &face, double eps)`  
*Split one volume according to intersections with a given face.*
- `void updateWithSplitFaces (shared_ptr< SurfaceModel > shell, shared_ptr< ftSurface > &face1, shared_ptr< ftSurface > &face2, std::vector< std::pair< ftEdge *, ftEdge * > > &replaced_wires)`  
*Specific functionality. Used from ftVolume::generateMissingBdSurf.*
- `int boundaryStatus (ftVolume *vol, shared_ptr< ftSurface > &bd_face, double tol)`

### 28.15.1 Detailed Description

This namespace contains service functions related to [ftVolume](#).

### 28.15.2 Function Documentation

28.15.2.1 `int Go::ftVolumeTools::boundaryStatus ( ftVolume * vol, shared_ptr< ftSurface > & bd_face, double tol )`

Given a boundary or trimming surface related to an [ftVolume](#), check the status and update stored information if any new boundary status information is computed

#### Parameters

|                      |                                                                              |
|----------------------|------------------------------------------------------------------------------|
| <code>vol</code>     | the volume from which the boundary status is to be checked                   |
| <code>bd_face</code> | the boundary face where the requested information should be fetched/computed |
| <code>tol</code>     | tolerance to check for surface coincidence                                   |

**Returns**

-1 = not a boundary surface, 0 = boundary surface corresponding to umin, 1 = boundary surface corresponding to umax, 2 = boundary surface corresponding to vmin, 3 = boundary surface corresponding to vmax, 4 = boundary surface corresponding to wmin, 5 = boundary surface corresponding to wmax

28.15.2.2 `std::vector<shared_ptr<ftVolume>> Go::ftVolumeTools::splitVolumes ( shared_ptr< ftVolume > & vol1, shared_ptr< ftVolume > & vol2, double eps, std::vector< int > & config )`

Split two volumes with regard to the intersections between the boundary surfaces corresponding to these two volumes

28.15.2.3 `std::vector<shared_ptr<ftVolume>> Go::ftVolumeTools::splitVolumes ( shared_ptr< ftVolume > & vol, shared_ptr< ftSurface > & face, double eps )`

Split one volume according to intersections with a given face.

28.15.2.4 `void Go::ftVolumeTools::updateWithSplitFaces ( shared_ptr< SurfaceModel > shell, shared_ptr< ftSurface > & face1, shared_ptr< ftSurface > & face2, std::vector< std::pair< ftEdge *, ftEdge * > > & replaced_wires )`

Specific functionality. Used from `ftVolume::generateMissingBdSurf`.

## 28.16 Go::GapRemoval Namespace Reference

Functionality for removal of gaps between two adjacent surfaces of various types.

**Functions**

- void `removeGapSpline` (`shared_ptr< SplineSurface > &srf1`, `shared_ptr< CurveOnSurface > &bd_cv1`, `double start1`, `double end1`, `shared_ptr< SplineSurface > &srf2`, `shared_ptr< CurveOnSurface > &bd_cv2`, `double start2`, `double end2`, `Point vertex1`, `Point vertex2`, `double epsge`, `bool *same_orientation=NULL`)
- `double removeGapTrim` (`shared_ptr< CurveOnSurface > &bd_cv1`, `double start1`, `double end1`, `shared_ptr< CurveOnSurface > &bd_cv2`, `double start2`, `double end2`, `Point vertex1`, `Point vertex2`, `double epsge`)
- `bool removeGapSplineTrim` (`shared_ptr< SplineSurface > &srf1`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv1`, `std::vector< double > start1`, `std::vector< double > end1`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv2`, `std::vector< double > start2`, `std::vector< double > end2`, `Point vertex1`, `Point vertex2`, `double epsge`)
- void `modifySplineSf` (`shared_ptr< ParamSurface > &srf1`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv1`, `std::vector< double > start1`, `std::vector< double > end1`, `shared_ptr< ParamSurface > &srf2`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv2`, `std::vector< double > start2`, `std::vector< double > end2`, `double epsge`)
- void `modifySplines` (`shared_ptr< ParamSurface > &srf1`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv1`, `std::vector< double > &start1`, `std::vector< double > &end1`, `shared_ptr< ParamSurface > &srf2`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv2`, `std::vector< double > &start2`, `std::vector< double > &end2`, `std::vector< Point > &vertex`, `double epsge`)
- void `removeGapSpline2` (`std::vector< shared_ptr< CurveOnSurface > > &bd_cv1`, `std::vector< double > &start1`, `std::vector< double > &end1`, `std::vector< shared_ptr< CurveOnSurface > > &bd_cv2`, `std::vector< double > &start2`, `std::vector< double > &end2`, `std::vector< Point > &vertex`, `double epsge`)

- `std::vector< shared_ptr< sideConstraintSet > >` `getCoefConstraints` (`shared_ptr< SplineCurve >` &crv1, `int` idx1, `shared_ptr< SplineCurve >` &crv2, `int` idx2, `double` tol)
- `shared_ptr< SplineCurve >` `replaceCurvePiece` (`shared_ptr< SplineCurve >` crv, `shared_ptr< SplineCurve >` sub\_crv, `double` par1, `int` cont1, `double` par2, `int` cont2)
- `shared_ptr< SplineSurface >` `getSplineAndBd` (`shared_ptr< ParamSurface >` psurf, `std::vector< shared_ptr< CurveOnSurface > >` &bd\_crvs)
- `void` `getBoundarySamples` (`std::vector< shared_ptr< CurveOnSurface > >` &all\_bd, `std::vector< shared_ptr< CurveOnSurface > >` &bd\_cvs, `std::vector< double >` &pts, `std::vector< double >` &pars, `std::vector< int >` &bd\_idx, `double` epsge)
- `bool` `modifyAtVertex` (`shared_ptr< SplineSurface >` srf, `Point` face\_param, `Point` vertex, `double` epsge)
- `void` `checkBoundaryDist` (`shared_ptr< CurveOnSurface >` bd1, `shared_ptr< CurveOnSurface >` bd2, `double` start1, `double` end1, `double` start2, `double` end2, `int` nmb\_sample, `double` &mdist1, `double` &mdist2)
- `void` `removeGapSpline` (`shared_ptr< SplineVolume >` &vol1, `shared_ptr< SurfaceOnVolume >` &bd\_sf1, `double` sf1\_start1, `double` sf1\_end1, `double` sf1\_start2, `double` sf1\_end2, `shared_ptr< SplineVolume >` &vol2, `shared_ptr< SurfaceOnVolume >` &bd\_sf2, `double` sf2\_start1, `double` sf2\_end1, `double` sf2\_start2, `double` sf2\_end2, `Point` vertex\_ll, `Point` vertex\_ur, `double` epsge, `int` orientation)

### 28.16.1 Detailed Description

Functionality for removal of gaps between two adjacent surfaces of various types.

Removal of gaps between two adjacent volumes No implementation

### 28.16.2 Function Documentation

**28.16.2.1** `void` `Go::GapRemoval::checkBoundaryDist` ( `shared_ptr< CurveOnSurface >` *bd1*, `shared_ptr< CurveOnSurface >` *bd2*, `double` *start1*, `double` *end1*, `double` *start2*, `double` *end2*, `int` *nmb\_sample*, `double` & *mdist1*, `double` & *mdist2* )

Compute the distance between trimming curves on adjacent surfaces along a common boundary.

#### Parameters

|               |                                                                                    |
|---------------|------------------------------------------------------------------------------------|
| <i>bd1</i>    | trimming curve on first surface                                                    |
| <i>bd2</i>    | trimming curve on second surface                                                   |
| <i>start1</i> | start parameter to the relevant piece of bd1                                       |
| <i>end1</i>   | end parameter to the relevant piece of bd1                                         |
| <i>start2</i> | start parameter to the relevant piece of bd2                                       |
| <i>end2</i>   | end parameter to the relevant piece of bd2                                         |
| <i>mdist1</i> | maximum distance between given trimming curves                                     |
| <i>mdist2</i> | maximum distance between the trimming curves projected onto the associated surface |

**28.16.2.2** `void` `Go::GapRemoval::getBoundarySamples` ( `std::vector< shared_ptr< CurveOnSurface > >` & *all\_bd*, `std::vector< shared_ptr< CurveOnSurface > >` & *bd\_cvs*, `std::vector< double >` & *pts*, `std::vector< double >` & *pars*, `std::vector< int >` & *bd\_idx*, `double` *epsge* )

Given the trimming curves of a bounded surface. Sort the curves followin boundaries of the underlying surface into the vector `bd_cvs`. The remaining curves are sampled and the corresponding points and parameter values are returned in the vectors `pts` and `pars`.

28.16.2.3 `std::vector<shared_ptr<sideConstraintSet> > Go::GapRemoval::getCoefConstraints ( shared_ptr<SplineCurve > & crv1, int idx1, shared_ptr< SplineCurve > & crv2, int idx2, double tol )`

Define linear constraints between coefficients on two curves entities representing the same trace to make the trace of the two curves identical.

28.16.2.4 `shared_ptr<SplineSurface> Go::GapRemoval::getSplineAndBd ( shared_ptr< ParamSurface > psurf, std::vector< shared_ptr< CurveOnSurface > > & bd_crvs )`

Fetch the underlying spline surface and trimming curves from a bounded surface

28.16.2.5 `bool Go::GapRemoval::modifyAtVertex ( shared_ptr< SplineSurface > srf, Point face_param, Point vertex, double epsge )`

Modify a surface to adapt to a given point, vertex, in the parameter value face\_param.

28.16.2.6 `void Go::GapRemoval::modifySplines ( shared_ptr< ParamSurface > & srf1, std::vector< shared_ptr< CurveOnSurface > > & bd_cv1, std::vector< double > & start1, std::vector< double > & end1, shared_ptr< ParamSurface > & srf2, std::vector< shared_ptr< CurveOnSurface > > & bd_cv2, std::vector< double > & start2, std::vector< double > & end2, std::vector< Point > & vertex, double epsge )`

Modify the underlying spline surface of srf1 to improve the adaption to given trimming curves.

28.16.2.7 `void Go::GapRemoval::modifySplineSf ( shared_ptr< ParamSurface > & srf1, std::vector< shared_ptr< CurveOnSurface > > & bd_cv1, std::vector< double > start1, std::vector< double > end1, shared_ptr< ParamSurface > & srf2, std::vector< shared_ptr< CurveOnSurface > > & bd_cv2, std::vector< double > start2, std::vector< double > end2, double epsge )`

Modify the underlying spline surface of srf1 to improve the adaption to given trimming curves.

28.16.2.8 `void Go::GapRemoval::removeGapSpline ( shared_ptr< SplineVolume > & vol1, shared_ptr< SurfaceOnVolume > & bd_sf1, double sf1_start1, double sf1_end1, double sf1_start2, double sf1_end2, shared_ptr< SplineVolume > & vol2, shared_ptr< SurfaceOnVolume > & bd_sf2, double sf2_start1, double sf2_end1, double sf2_start2, double sf2_end2, Point vertex_ll, Point vertex_ur, double epsge, int orientation )`

We average the volumes along the matching faces on the rectangular domain given by vertex lower left and upper right (assuming that such a domain is well defined).

28.16.2.9 `void Go::GapRemoval::removeGapSpline ( shared_ptr< SplineSurface > & srf1, shared_ptr< CurveOnSurface > & bd_cv1, double start1, double end1, shared_ptr< SplineSurface > & srf2, shared_ptr< CurveOnSurface > & bd_cv2, double start2, double end2, Point vertex1, Point vertex2, double epsge, bool * same_orientation = NULL )`

Both surfaces are non-trimmed spline surfaces and the common boundary are described by [CurveOnSurface](#) entities Remove gap by averaging coefficients at the common boundary. May increase the associated spline spaces.

```
28.16.2.10 void Go::GapRemoval::removeGapSpline2 (std::vector< shared_ptr< CurveOnSurface > > & bd_cv1,
std::vector< double > & start1, std::vector< double > & end1, std::vector< shared_ptr< CurveOnSurface
> > & bd_cv2, std::vector< double > & start2, std::vector< double > & end2, std::vector< Point > &
vertex, double epsge)
```

Both surfaces are non-trimmed spline surfaces and the common boundary are described by [CurveOnSurface](#) entities. Remove gap by defining conditions between coefficients at the common boundary between the two surface and modify both surfaces accordingly.

```
28.16.2.11 bool Go::GapRemoval::removeGapSplineTrim (shared_ptr< SplineSurface > & srf1, std::vector<
shared_ptr< CurveOnSurface > > & bd_cv1, std::vector< double > start1, std::vector< double > end1,
std::vector< shared_ptr< CurveOnSurface > > & bd_cv2, std::vector< double > start2, std::vector<
double > end2, Point vertex1, Point vertex2, double epsge)
```

Both surfaces are trimmed and have an underlying spline surface. The common boundary are described by [CurveOnSurface](#) entities limited by bounding parameters. Sub curves of the same curve on surface entity may occur several times, but are split to have correspondance between the two surfaces along the common boundary.

```
28.16.2.12 double Go::GapRemoval::removeGapTrim (shared_ptr< CurveOnSurface > & bd_cv1, double start1,
double end1, shared_ptr< CurveOnSurface > & bd_cv2, double start2, double end2, Point vertex1,
Point vertex2, double epsge)
```

Both surfaces are trimmed of some type and the common boundary are described by [CurveOnSurface](#) entities.

```
28.16.2.13 shared_ptr< SplineCurve > Go::GapRemoval::replaceCurvePiece (shared_ptr< SplineCurve > crv,
shared_ptr< SplineCurve > sub_crv, double par1, int cont1, double par2, int cont2)
```

Replace a sub curve (between par1 and par2) in a given spline curve by a modified curve piece. The continuity at the joints are given by cont1 and cont2.

## 28.17.1 Function Documentation

28.17.1.1 `int GO_API Go::GeometryTools::analyzePeriodicity ( const SplineCurve & cv, double knot_tol = 1e-12 )`

Analyze periodicity of curve based on number of repeating knots and control points. The return value is -1 if the curve ends are disjoint, otherwise k if cv is  $C^k$  continuous. These are sufficient but not necessary conditions for periodicity, so it is possible that a call to [analyzePeriodicityDerivs\(\)](#) will yield a higher degree of periodicity.

### Parameters

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>cv</i>       | the curve to analyse                              |
| <i>knot_tol</i> | the tolerance used when comparing knot intervals. |

### Returns

-1 if the curve ends are disjoint, or k if the curve is proven to be  $C^k$  continuous.

28.17.1.2 `int GO_API Go::GeometryTools::analyzePeriodicity ( const SplineSurface & sf, int direction, double knot_tol = 1e-12 )`

Analyze periodicity of surface based on number of repeating knots and control points. The return value is -1 if the surface edges are disjoint, otherwise k if sf is  $C^k$  continuous across the seam. These are sufficient but not necessary conditions for periodicity, so it is possible that a call to [analyzePeriodicityDerivs\(\)](#) will yield a higher degree of periodicity. The current implementation is quite slow, and not optimized for speed.

### Parameters

|                  |                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sf</i>        | reference to the <a href="#">SplineSurface</a> to be analyzed                                                                            |
| <i>direction</i> | specify 'direction' to be '0' to check for periodicity in the first parameter direction, or '1' to check the second parameter direction. |
| <i>knot_tol</i>  | the tolerance used when comparing knot intervals                                                                                         |

### Returns

-1 if the surface edges are disjoint, otherwise k if the

28.17.1.3 `int GO_API Go::GeometryTools::analyzePeriodicity ( const BsplineBasis & basis, double knot_tol = 1e-12 )`

Analyze periodicity of basis based on number of repeating knots. The return value is -1 if there is no repeating (or order-tuple end knots), up to k if there are (order-1-k)-tuple end knots and sufficient repeats for a  $C^k$  curve. This is mostly a helper function for the curve and surface analysis functions.

#### Parameters

|                 |                                                            |
|-----------------|------------------------------------------------------------|
| <i>basis</i>    | reference to the <a href="#">BsplineBasis</a> to analyze   |
| <i>knot_tol</i> | the tolerance used when comparing knots and knot intervals |

#### Returns

-1 if there is no repeating (or order-tuple end knots), up to k if there are (order-1-k)-tuple end knots and sufficient repeats for a  $C^k$  curve.

28.17.1.4 `int GO_API Go::GeometryTools::analyzePeriodicityDerivs ( const ParamCurve & cv, int max_derivs, double tol = 1e-14 )`

Analyze periodicity of curve based on evaluating derivatives at both endpoints. The return value is -1 if the curve ends are disjoint, otherwise k if cv is  $C^k$  continuous. A maximum of max\_derivs derivatives are computed, so the analysis cannot yield a higher return value than max\_derivs. The tolerance is the amount the point and derivatives are allowed to be different at the two ends. The default is quite tight!

#### Parameters

|                   |                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------|
| <i>cv</i>         | the curve to be analyzed for periodicity                                                          |
| <i>max_derivs</i> | the maximum of computed derivatives (the analysis can not detect continuities beyond this value). |
| <i>tol</i>        | the tolerance used when comparing points and derivatives for approximate equality                 |

#### Returns

-1 if the curve ends are disjoint, k if the curve is proven to be  $C^k$  continuous.

28.17.1.5 `int GO_API Go::GeometryTools::analyzePeriodicityDerivs ( const SplineSurface & sf, int direction, int max_derivs, double tol = 1e-14 )`

Analyze periodicity of surface based on evaluating derivatives at opposing ends of the surface. The return value is -1 if the surface edges are disjoint, otherwise k if sf is  $C^k$  continuous across the seam. These are sufficient but not necessary conditions for periodicity, so it is possible that a call to [analyzePeriodicityDerivs\(\)](#) will yield a higher degree of periodicity. The current implementation is quite slow, and not optimized for speed.

#### Parameters

|                   |                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>sf</i>         | the <a href="#">SplineSurface</a> to analyze for periodicity                                                              |
| <i>direction</i>  | the parameter direction to check for periodicity (0 to check in the first parameter direction, 1 to check in the second). |
| <i>max_derivs</i> | the maximum of computed derivatives (the analysis cannot detect continuities beyond this value)                           |
| <i>tol</i>        | the tolerance used when comparing points and derivatives for approximate equality.                                        |

## Returns

-1 if the surface edges are disjoint, or k if the surface is proven to be  $C^k$  continuous across the seam.

28.17.1.6 `void GO_API Go::GeometryTools::averageBoundaryCoefs ( shared_ptr< SplineSurface > & srf1, int bd1, bool keep_first, shared_ptr< SplineSurface > & srf2, int bd2, bool keep_second, bool found_corner1, Point corner1, bool found_corner2, Point corner2, bool opposite )`

Average specified boundary coefficients between two spline surfaces to ensure a C0 transition

28.17.1.7 `bool GO_API Go::GeometryTools::checkConstantCoef ( SplineCurve & cv, int idx, double val, double max_dist, double tol )`

Check if a curve coefficient is equal to a constant in a specified dimension provided it already lies close

28.17.1.8 `void GO_API Go::GeometryTools::curveKinks ( const SplineCurve & cv, double tol, double ang_tol, std::vector< double > & c1_disconts, std::vector< double > & g1_disconts )`

Find parameter values where a curve is G1- or C1-discontinuous.

28.17.1.9 `shared_ptr<SplineCurve> GO_API Go::GeometryTools::curveSum ( const SplineCurve & crv1, double fac1, const SplineCurve & crv2, double fac2, double num_tol = 1e-05 )`

Addition of two signed SplineCurves, i.e. this function can also be used for subtraction. The curves is assumed to live on the same parameter domain, but may have different knot vectors. resulting curve = fac1 \* crv1 + fac2 \* crv2

## Parameters

|                |                                                                                |
|----------------|--------------------------------------------------------------------------------|
| <i>crv1</i>    | the first of the curves to be added                                            |
| <i>fac1</i>    | multiplicative factor of the first curve                                       |
| <i>crv2</i>    | the second of the curves to be added                                           |
| <i>fac2</i>    | multiplicative factor of the second curve                                      |
| <i>num_tol</i> | tolerance used when unifying the spline spaces in which 'crv1' and 'crv2' lie. |

## Returns

shared pointed to a newly created [SplineCurve](#) which is the sum of 'crv1' and 'crv2'.

28.17.1.10 `bool GO_API Go::GeometryTools::degenerateToCurve ( const SplineSurface & srf, bool dir_u, double tol )`

Check if a given spline surface degenerates to a curve within a given tolerance

28.17.1.11 `void GO_API Go::GeometryTools::estimateIsoCurveLength ( const SplineSurface & srf, bool dir_u, double par, double & length )`

estimate the length of an iso-curve on the surface

## Parameters

|               |                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>srf</i>    | the surface containing the iso-curve                                                                                               |
| <i>dir_u</i>  | 'true' if the iso-curve is along the first parameter (second parameter fixed), 'false' if it is the first parameter that is fixed. |
| <i>par</i>    | parameter value for the fixed parameter                                                                                            |
| <i>length</i> | returns the estimated length of the iso-curve                                                                                      |

28.17.1.12 void **GO\_API** Go::GeometryTools::estimateSurfaceSize ( const ParamSurface & *srf*, double & *length\_u*, double & *length\_v*, double \* *area* = NULL )

Rough estimate of the size of a parametric surface

## Parameters

|                 |                                                                                |
|-----------------|--------------------------------------------------------------------------------|
| <i>srf</i>      | the surface we want to estimate the size of                                    |
| <i>length_u</i> | the estimated average length of the surface, moving along the first parameter  |
| <i>length_v</i> | the estimated average length of the surface, moving along the second parameter |

28.17.1.13 void **GO\_API** Go::GeometryTools::findDominant ( const SplineSurface & *surface*, Vector3D & *dominant\_u*, Vector3D & *dominant\_v* )

Finds the "dominant u- and v-vectors" for a surface, defined to be the sum of all the vectors pointing from one control point to the next in the u- and v-directions

## Parameters

|                   |                                               |
|-------------------|-----------------------------------------------|
| <i>surface</i>    | the surface we want to analyze                |
| <i>dominant_u</i> | returns the dominant u-vector for the surface |
| <i>dominant_v</i> | returns the dominant v-vector for the surface |

28.17.1.14 void **GO\_API** Go::GeometryTools::getGnJoints ( const ParamCurve & *curve*, const std::vector< double > & *cont*, std::vector< double > & *gn\_joints* )

Partition the given curve into segments where each segment is at least  $G^n$  continuous (currently supporting up to  $G^2$  continuity).

## Parameters

|              |                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>curve</i> | the curve to analyze                                                                                                                                                                                                                                                      |
| <i>cont</i>  | the tolerance used for defining continuity. <i>cont</i> [0] is the tolerance used for defining the $G^0$ continuity, <i>cont</i> [1] is used for checking $G^1$ continuity, etc. The length of this vector also determines 'n' ('n' is equal to <i>cont</i> .size() - 1). |

## Return values

|                  |                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gn_joints</i> | returns the parameter values where one segment stops and the next begins. The vector will at least contain two values (the start and end parameter of the curve). |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**28.17.1.15** `void GO_API Go::GeometryTools::getGnJoints ( const CurveLoop & loop, const std::vector< double > & cont, std::vector< std::vector< double > > & gn_joints )`

Partition a given [CurveLoop](#) into segments where each segment is at least  $G^n$  continuous (currently supporting up to  $G^2$  continuity).

## Parameters

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>loop</i>      | the <a href="#">CurveLoop</a> to analyze                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>cont</i>      | the tolerance used for defining continuity. <code>cont[0]</code> is the tolerance used for defining the $G^0$ continuity, <code>cont[1]</code> is used for checking $G^1$ continuity, etc. The length of this vector also determines 'n' ('n' is equal to <code>cont.size() - 1</code> ).                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>gn_joints</i> | a vector of a vector, reporting the result of the analysis. The outer vector contains one entry per curve in the <a href="#">CurveLoop</a> . This entry contains the parameters for which that curve must be split in order to obtain $G^n$ segments. NB: the start- and end parameters are NOT included here, as opposed to the result obtained from the other <a href="#">getGnJoints()</a> function. The exception to this is when there is an $G^n$ discontinuity at the transition between the curve 'i-1' and curve 'i' in the <a href="#">CurveLoop</a> . To indicate this, the start parameter value for curve 'i' will be included in the corresponding entry in 'gn_joints'. |

**28.17.1.16** `double GO_API Go::GeometryTools::getKnotAtLargestInterval ( const BsplineBasis & basis )`

Return the mid parameter of the largest parameter interval in a given B-spline basis. If several knot intervals have the same size, the first is returned.

**28.17.1.17** `std::pair<double, double> GO_API Go::GeometryTools::getLargestParameterInterval ( const BsplineBasis & basis )`

Return the start and end parameter corresponding to the largest parameter interval in a given B-spline basis. If several knot intervals have the same size, the first is returned.

**28.17.1.18** `std::vector<double> GO_API Go::GeometryTools::getRotationMatrix ( const Point & unit_axis_dir, double alpha )`

Compute the elements of the matrix describing a rotation or a given number of radians around a given axis going through the origin.

## Parameters

|                      |                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>unit_axis_dir</i> | this vector defines the axis of rotation. It must be of unit length, although this is not checked by the function. |
| <i>alpha</i>         | the angle of rotation, in radians                                                                                  |

**Returns**

a vector containing the matrix elements of the corresponding rotation matrix, stored row-wise.

**28.17.1.19** void **GO\_API** Go::GeometryTools::insertKnotsEvenly ( **BsplineBasis** & *basis*, int *num\_knots* )

Insert *num\_knots* new knots in the *num\_knots* largest knot intervals in the B-spline basis basis. The knots are inserted one by one. Thus, more than one knot may be inserted in one knot interval of the initial basis. And we do not end up with the most even distribution of knots possible.

**28.17.1.20** void **GO\_API** Go::GeometryTools::insertKnotsEvenly ( **BsplineBasis** & *basis*, double *tmin*, double *tmax*, int *num\_knots*, double *knot\_diff\_tol* = 1e-05 )

Insert *num\_knots* new knots in the *num\_knots* largest knot intervals in the B-spline basis basis in the parameter interval [*tmin*,*tmax*]. The knots are inserted one by one. Thus, more than one knot may be inserted in one knot interval of the initial basis. And we do not end up with the most even distribution of knots possible.

**28.17.1.21** bool **GO\_API** Go::GeometryTools::isCoincident ( const **ParamCurve** & *cv1*, const **ParamCurve** & *cv2*, double *epsge* )

Returns true if the curves are approximately coincident (that is, they have the same parameter space and overlap in space). The function uses a (possibly high) number of closest point calculations to check for spatial coincidence.

**Parameters**

|              |                                                                              |
|--------------|------------------------------------------------------------------------------|
| <i>cv1</i>   | the first curve to check for coincidence                                     |
| <i>cv2</i>   | the second curve to check for coincidence                                    |
| <i>epsge</i> | the tolerance for specifying what we mean by <i>approximately</i> coincident |

**Returns**

'true' if the curves are found to be approximately coincident, 'false' otherwise.

**28.17.1.22** shared\_ptr<**SplineSurface**> **GO\_API** Go::GeometryTools::joinPatches ( const std::vector< shared\_ptr<**SplineSurface**>> & *patches*, const **SplineSurface** & *spline\_space* )

Join patches with continuity according to input *basis\_u* & *basis\_v*. The patches are assumed to be in Bezier form, and form a continuous set. There should be *num\_u* x *num\_v* patches, where *num\_u* = *numcoefs\_u*/*order\_u* and *num\_v* = *numcoefs\_v*/*order\_v* (as given by *basis\_u* and *basis\_v*).

**28.17.1.23** void **GO\_API** Go::GeometryTools::makeBdDegenerate ( **SplineSurface** & *srf*, int *bd\_idx* )

Make a specified surface boundary exactly degenerate.

28.17.1.24 void **GO\_API** Go::GeometryTools::makeUnionKnots ( std::vector< **BsplineBasis** > & *bbasis*, double *tol*, std::vector< double > & *union\_knots* )

Compute the union of a set of knot vectors.

28.17.1.25 void **GO\_API** Go::GeometryTools::makeUnionKnots ( std::vector< std::vector< double > > & *knots*, double *tol*, std::vector< double > & *union\_knots* )

28.17.1.26 bool **GO\_API** Go::GeometryTools::negativeProj ( const **SplineSurface** & *surface*, const Array< **Vector3D**, 2 > & *refvector*, const double *eps* = 0.0 )

Returns true if any vector difference between neighboring control points in the u- or v-directions has negative projection on the given reference vector.

#### Parameters

|                  |                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>surface</i>   | the <a href="#">SplineSurface</a> containing the control points                                                                       |
| <i>refvector</i> | the vector onto which we carry out the projection                                                                                     |
| <i>eps</i>       | tolerance used when defining whether a vector has a negative projection onto 'refvector' (the scalar product must be less than -eps). |

#### Returns

'true' if we have found a difference between neighboring control points that has a negative projection on the reference vector.

28.17.1.27 shared\_ptr<**ParamCurve**> **GO\_API** Go::GeometryTools::projectCurve ( shared\_ptr< **ParamCurve** > *incurve*, const **Point** & *normal*, bool *planar* )

Project a 3D parametric curve into a given plane. The curve can be returned either as a 3D curve lying in the plane or as a 2D curve. In the latter case, the coordinate system is rotated such that the given plane normal coincides with the z-axis.

#### Parameters

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>incurve</i> | the curve to project                                   |
| <i>normal</i>  | the normal to the plane of projection                  |
| <i>planar</i>  | 'true' if we want the returned curve to be a 2D curve. |

#### Returns

a shared pointer to a newly constructed, planar [SplineCurve](#) represented as a parametric curve expressing the projection of 'incurve' onto the given plane.

28.17.1.28 shared\_ptr<**SplineCurve**> **GO\_API** Go::GeometryTools::projectCurve ( const **SplineCurve** & *incurve*, const **Point** & *normal*, bool *planar* )

Project a 3D [SplineCurve](#) into a given plane. The curve can be returned either as a 3D curve lying in the plane or as a 2D curve. In the latter case, the coordinate system is rotated such that the given plane normal coincides with

the z-axis.

#### Parameters

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>incurve</i> | the curve to project                                   |
| <i>normal</i>  | the normal to the plane of projection                  |
| <i>planar</i>  | 'true' if we want the returned curve to be a 2D curve. |

#### Returns

a shared pointer to a newly constructed, planar [SplineCurve](#) expressing the projection of 'incurve' onto the given plane.

**28.17.1.29** `shared_ptr<SplineSurface> GO_API Go::GeometryTools::representCurveAsSurface ( const SplineCurve & curve, int cv_dir, const BsplineBasis & other_bas, bool rational )`

Describe a curve as surface in a given direction. The surface output is rational if the argument *rational* is set to 'true'. In that case the curve is supposed to live in homogenous space. Describe a curve as a lower-dimensional surface in a given direction.

#### Parameters

|                  |                                                                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>curve</i>     | the curve that we want to express as a surface                                                                                                                                                                                                                     |
| <i>cv_dir</i>    | If this variable is set to '1', then the curve's parameter will become the <i>first</i> parameter in the generated surface. If it is set to '2', the curve's parameter will become the <i>second</i> parameter in the generated surface. Other values are illegal. |
| <i>other_bas</i> | the <a href="#">BsplineBasis</a> for the additional parameter direction.                                                                                                                                                                                           |
| <i>rational</i>  | define whether the generated surface shall be specified as <i>rational</i> or not.                                                                                                                                                                                 |

#### Returns

a shared pointer to a new [SplineSurface](#), expressing the curve in a space of lower dimensionality.

**28.17.1.30** `shared_ptr<SplineCurve> GO_API Go::GeometryTools::representSurfaceAsCurve ( const SplineSurface & surface, int cv_dir )`

Describe a surface as a high-dimensional curve in a given direction. If the surface is rational, the curve will be non-rational and living in the homogenous space.

#### Parameters

|                |                                                                                                                                                                                                                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>surface</i> | the surface to express as a curve                                                                                                                                                                                                                                                                                                                             |
| <i>cv_dir</i>  | the parameter direction that will be kept when defining the curve (the other one will disappear, as the control points in this direction will be lumped together and expressed as single control points in a higher-dimensional space. 'cv_dir' takes either the value '1' (keep the first parameter direction) or '2' (keep the second parameter direction). |

**Returns**

shared pointer to a new [SplineCurve](#), expressing the surface as a curve in a high-dimensional space.

28.17.1.31 void `GO_API Go::GeometryTools::rotateLineCloud ( Point rot_axis, double alpha, LineCloud & lc )`

Rotate the given [LineCloud](#) a certain angle around a given axis.

**Parameters**

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <i>rot_axis</i> | the axis of rotation. It does not have to be normalized, but must of course be nonzero. |
| <i>alpha</i>    | the angle of rotation, given in radians                                                 |
| <i>lc</i>       | reference to the <a href="#">LineCloud</a> that is to be rotated                        |

28.17.1.32 void `GO_API Go::GeometryTools::rotatePoint ( Point rot_axis, double alpha, double * space_pt )`

Rotate the given 3D point a certain angle around a certain axis.

**Parameters**

|                              |                                                                                                                                          |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>rot_axis</i>              | the axis of rotation. It does not have to be normalized, but must of course be nonzero.                                                  |
| <i>alpha</i>                 | the angle of rotation, given in radians                                                                                                  |
| <i>space</i> ↔<br><i>_pt</i> | pointer to the memory location where the 3D coordinates of the point are stored. These will be overwritten with the rotated coordinates. |

28.17.1.33 void `GO_API Go::GeometryTools::rotatePoint ( Point rot_axis, double alpha, Point & space_pt )`

Rotate the given 3D point a certain angle around a certain axis.

**Parameters**

|                              |                                                                                              |
|------------------------------|----------------------------------------------------------------------------------------------|
| <i>rot_axis</i>              | the axis of rotation. It does not have to be normalized, but must of course be nonzero.      |
| <i>alpha</i>                 | the angle of rotation, given in radians                                                      |
| <i>space</i> ↔<br><i>_pt</i> | reference to teh point to be rotated. This will be overwritten with the rotated coordinates. |

28.17.1.34 void `GO_API Go::GeometryTools::rotateSplineCurve ( Point rot_axis, double alpha, SplineCurve & cv )`

Rotate the given [SplineCurve](#) a certain angle around a given axis.

**Parameters**

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <i>rot_axis</i> | the axis of rotation. It does not have to be normalized, but must of course be nonzero. |
| <i>alpha</i>    | the angle of rotation, given in radians                                                 |
| <i>cv</i>       | reference to the curve that is to be rotated                                            |

28.17.1.35 void **GO\_API** Go::GeometryTools::rotateSplineSurf ( Point *rot\_axis*, double *alpha*, SplineSurface & *sf* )

Rotate the given [SplineSurface](#) a certain angle around a given axis.

#### Parameters

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <i>rot_axis</i> | the axis of rotation. It does not have to be normalized, but must of course be nonzero. |
| <i>alpha</i>    | the angle of rotation, given in radians                                                 |
| <i>sf</i>       | reference to the surface that is to be rotated.                                         |

28.17.1.36 void Go::GeometryTools::setParameterDomain ( std::vector< shared\_ptr< BoundedSurface > > & *sfs*, double *u1*, double *u2*, double *v1*, double *v2* )

Reparameterize a set of bounded surfaces to the same domain.

28.17.1.37 void **GO\_API** Go::GeometryTools::setSfBdCoefToConst ( SplineSurface & *sf*, int *bd\_idx*, int *idx\_d*, double *val*, double *deg\_tol* )

Modify surface along specified boundary to match a specific constant in one direction. Currently only non-rational surfaces

28.17.1.38 void **GO\_API** Go::GeometryTools::splitCurveIntoSegments ( const SplineCurve & *cv*, std::vector< SplineCurve > & *seg* )

Split a spline curve into Bezier segments.

28.17.1.39 std::vector<shared\_ptr<SplineSurface>> **GO\_API** Go::GeometryTools::splitInKinks ( const SplineSurface & *sf*, const std::vector< double > & *u\_kinks*, const std::vector< double > & *v\_kinks* )

Extract sub patches from the surface given by input parameters.

28.17.1.40 void **GO\_API** Go::GeometryTools::splitSurfaceIntoPatches ( const SplineSurface & *sf*, std::vector< SplineSurface > & *pat* )

Splits a spline surface into Bezier patches.

28.17.1.41 void **GO\_API** Go::GeometryTools::surfaceKinks ( const SplineSurface & *sf*, double *max\_normal\_angle*, std::vector< double > & *g1\_disc\_u*, std::vector< double > & *g1\_disc\_v*, bool *compute\_g1\_disc* = true )

Surface assumed to be continuous. Return parameter values failing to achieve G1-continuity.

28.17.1.42 `shared_ptr<SplineSurface> GO_API Go::GeometryTools::surfaceSum ( const SplineSurface & sf1, double fac1, const SplineSurface & sf2, double fac2, double num_tol = 1e-05 )`

28.17.1.43 `void GO_API Go::GeometryTools::translateLineCloud ( const Point & trans_vec, LineCloud & lc )`

Translate the given [LineCloud](#) by `trans_vec`.

28.17.1.44 `void GO_API Go::GeometryTools::translateSplineCurve ( const Point & trans_vec, SplineCurve & cv )`

Translate the given [SplineCurve](#) by `trans_vec`.

28.17.1.45 `void GO_API Go::GeometryTools::translateSplineSurf ( const Point & trans_vec, SplineSurface & sf )`

Translate the given [SplineSurface](#) by `trans_vec`.

28.17.1.46 `void GO_API Go::GeometryTools::unifyCurveSplineSpace ( std::vector< shared_ptr< SplineCurve > > & curves, double tol )`

Make sure that a set of curves live on the same knot vector tol-equal knots are set equal (i.e. if they differ within tol).

28.17.1.47 `void GO_API Go::GeometryTools::unifySurfaceSplineSpace ( std::vector< shared_ptr< SplineSurface > > & surfaces, double tol, int dir = 0 )`

Make sure that a set of surfaces live on the same knot vectors tol-equal knots are set equal (i.e. if they differ within tol). `dir` 0 means both, 1 is u, 2 is v

28.17.1.48 `void GO_API Go::GeometryTools::unifySurfaceSplineSpaceOneDir ( std::vector< shared_ptr< SplineSurface > > & surfaces, double tol, bool unify_u_dir )`

Make sure that a set of surfaces live on the same knot vectors in one parameter direction. tol-equal knots are set equal (i.e. if they differ within tol). Nothing is changed in the other parameter direction (as opposed to [unifySurfaceSplineSpace\(\)](#) where orders are raised to same value for all surfaces in both directions) Warning! Objects being pointed to may be recreated inside function. Remember to update other shared pointers if needed.

#### Parameters

|                          |                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>surfaces</code>    | Surfaces to end up with common knot vectors                                                               |
| <code>tol</code>         | tolerance for identifying equal knot values                                                               |
| <code>unify_u_dir</code> | if 'true', unify bases in first parameter direction if 'false', unify bases in second parameter direction |

## 28.18 Go::HahnsSurfaceGen Namespace Reference

## Functions

- `std::vector< shared_ptr< Go::ParamSurface > > constructPolygonalSurface` (`std::vector< shared_ptr< Go::ParamCurve > > &bnd_curves`, `std::vector< shared_ptr< Go::ParamCurve > > &cross_curves`, `double neighbour_tol`, `double kink_tol`, `double knot_diff_tol`)
- `std::vector< shared_ptr< Go::ParamSurface > > constructHahnsSurface` (`std::vector< shared_ptr< Go::SplineCurve > > &bnd_curves`, `std::vector< shared_ptr< Go::SplineCurve > > &mod_cross_curves`, `double neighbour_tol`, `double kink_tol`, `double knot_diff_tol`)

### 28.18.1 Detailed Description

This namespace contains functions used to create a number of surface covering a whole defined by of a number of boundary curves ( $3 \leq \text{nmb\_cvs} \leq 6$ ). Hahns method is used in the construction. Typically used for patching a model in which one or more surfaces are missing.

### 28.18.2 Function Documentation

**28.18.2.1** `std::vector<shared_ptr<Go::ParamSurface> > Go::HahnsSurfaceGen::constructHahnsSurface ( std::vector< shared_ptr< Go::SplineCurve > > & bnd_curves, std::vector< shared_ptr< Go::SplineCurve > > & mod_cross_curves, double neighbour_tol, double kink_tol, double knot_diff_tol )`

Given input of `bnd_curves` and `cross_tangent` curves, create the corresponding Hahns Surfaces. Assuming input curves fulfill corner conditions. All curves expected to live in 3-dimensional space.

#### Parameters

|                         |                                                    |
|-------------------------|----------------------------------------------------|
| <i>bnd_curves</i>       | edge curves for the Hahns Surface.                 |
| <i>mod_cross_curves</i> | corresponding cross tangent curves.                |
| <i>neighbour_tol</i>    | allowed distance between corresponding end points. |
| <i>kink_tol</i>         | allowed angle between corresponding tangents.      |
| <i>knot_diff_tol</i>    | parametric tolerance for equality of knots.        |

#### Returns

vector containing the Hahns Surface.

**28.18.2.2** `std::vector<shared_ptr<Go::ParamSurface> > Go::HahnsSurfaceGen::constructPolygonalSurface ( std::vector< shared_ptr< Go::ParamCurve > > & bnd_curves, std::vector< shared_ptr< Go::ParamCurve > > & cross_curves, double neighbour_tol, double kink_tol, double knot_diff_tol )`

The routine which actually creates vector of blending surfaces, with given curves as their total bnd curve. # of return surfaces equals # of curves. All bnd curves share orientation (clockwise), and all cross curves point inwards. A missing cross curve is indicated by a 0 pointer. `bnd_curves` must form a loop. As we approximate modified cross curves, we include parameters to denote the exactness of the approximation. All curves expected to live in 3-dimensional space.

#### Parameters

|                   |                                    |
|-------------------|------------------------------------|
| <i>bnd_curves</i> | edge curves for the Hahns Surface. |
|-------------------|------------------------------------|

## Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <i>cross_curves</i>  | corresponding cross tangent curves.                |
| <i>neighbour_tol</i> | allowed distance between corresponding end points. |
| <i>kink_tol</i>      | allowed angle between corresponding tangents.      |
| <i>knot_diff_tol</i> | parametric tolerance for equality of knots.        |

## Returns

vector containing the Hahns Surface.

### 28.21.1 Detailed Description

This namespace contains functions used to create lofted surfaces.

### 28.21.2 Function Documentation

#### 28.21.2.1 `SplineSurface* Go::LoftSurfaceCreator::loftNonrationalSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, std::vector< double >::iterator first_param, int nmb_crvs )`

Create a lofting surface interpolating the input curves in the input parameters. The input curves are expected to have identical B-spline space. Either all or none of the curves are expected to be rational. In case the curves are rational, we also loft the denominator function. In this way, we might risk that the resulting surface has negative control points, this must be handled by the calling function. The returned lofted surface will be non-rational if the curves are non-rational.

#### Parameters

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface.                       |
| <i>first_param</i> | iso parameter to corresponding curve referred to by <i>first_curve</i> . |
| <i>nmb_crvs</i>    | the number of curves referred to by <i>first_curve</i> .                 |

#### Returns

pointer to the created lofting surface.

#### 28.21.2.2 `SplineSurface* Go::LoftSurfaceCreator::loftRationalSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, std::vector< double >::iterator first_param, int nmb_crvs )`

Create a lofting surface interpolating the input rational curves in the input parameters by Hermite interpolation, to ensure positive denominator function. The input curves are expected to have identical B-spline space. All of the curves are expected to be rational. The returned lofted surface will also be rational.

#### Parameters

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface.                       |
| <i>first_param</i> | iso parameter to corresponding curve referred to by <i>first_curve</i> . |
| <i>nmb_crvs</i>    | the number of curves referred to by <i>first_curve</i> .                 |

#### Returns

pointer to the created lofting surface.

#### 28.21.2.3 `SplineSurface* Go::LoftSurfaceCreator::loftSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, int nmb_crvs )`

Create a lofting surface based on the input curves. The curves are not changed during the lofting process. The curves must all lie in the same space

## Parameters

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface.       |
| <i>nmb_crvs</i>    | the number of curves referred to by <i>first_curve</i> . |

## Returns

pointer to the created lofting surface.

**28.21.2.4** `SplineSurface*` `Go::LoftSurfaceCreator::loftSurface ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, std::vector< double >::iterator first_param, int nmb_crvs )`

Create a lofting surface interpolating the input curves in the input parameters. The curves are not changed during the lofting process. The curves must all lie in the same space

## Parameters

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface.                       |
| <i>first_param</i> | iso parameter to corresponding curve referred to by <i>first_curve</i> . |
| <i>nmb_crvs</i>    | the number of curves referred to by <i>first_curve</i> .                 |

## Returns

pointer to the created lofting surface.

**28.21.2.5** `SplineSurface*` `Go::LoftSurfaceCreator::loftSurface ( std::vector< shared_ptr< SplineCurve > > & loft_curves, int nmb_crvs )`

Create a lofting surface based on the input curves. The curves are changed during the lofting process. The curves must all lie in the same space.

## Parameters

|                    |                             |
|--------------------|-----------------------------|
| <i>loft_curves</i> | the input curves.           |
| <i>nmb_crvs</i>    | the number of input curves. |

## Returns

pointer to the created lofting surface.

**28.21.2.6** `SplineSurface*` `Go::LoftSurfaceCreator::loftSurfaceFromUnifiedCurves ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, std::vector< double >::iterator first_param, int nmb_crvs )`

Create a lofting surface interpolating the input curves in the input parameters. The input curves are expected to have identical B-spline space. Either all or none of the curves are expected to be rational. ??? The returned lofted surface will be rational if and only if the curves are rational.

## Parameters

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <i>first_curve</i> | iterator to first iso-curve in the lofted surface.                       |
| <i>first_param</i> | iso parameter to corresponding curve referred to by <i>first_curve</i> . |
| <i>nmb_crvs</i>    | the number of curves referred to by <i>first_curve</i> .                 |

## Returns

pointer to the created lofting surface.

**28.21.2.7** void `Go::LoftSurfaceCreator::makeLoftParams ( std::vector< shared_ptr< SplineCurve > >::const_iterator first_curve, int nmb_crvs, double param_length, std::vector< double > &params )`

Calculate iso parameters for the input curves. The curves are expected to be ordered, i.e. corresponding to increasing iso parameters. Curves are given iso-parameters in the range 0.0 to *param\_length*. All the parameter differences between two neighbouring curves will be proportional to the quadratic mean of the distance between corresponding control points, i.e. if, for two curves  $S=first\_curve[i]$  and  $T=first\_curve[i+1]$ ,  $Q$  is the quadratic mean of the distance between corresponding control points of  $S$  and  $T$ , and  $P$  is the difference between the calculated parameter values for  $S$  and  $T$ , then the ratio  $Q/P$  is the same for all  $i$ .

## Parameters

|                     |                                                   |
|---------------------|---------------------------------------------------|
| <i>first_curve</i>  | iterator to first iso curve.                      |
| <i>nmb_crvs</i>     | the number of input curves.                       |
| <i>param_length</i> | length of parameter domain.                       |
| <i>params</i>       | the computed iso parameters for the input curves. |

**28.21.2.8** `std::vector<shared_ptr<SplineCurve> > Go::LoftSurfaceCreator::unifiedCurvesCopy ( std::vector< shared_ptr< SplineCurve > >::iterator first_curve, int nmb_crvs )`

Create a vector of curves holding a copy of the input curves, but where the spline bases have been changed (reparametrized, knot inserted and order raised) so that the B-spline spaces for the new curves all are identical, and where all curves are now rational if at least one of the input curves were rational. The input curves are not changed during the process. The curves must all lie in the same space.

## Parameters

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <i>first_curve</i> | iterator to first input curve.                           |
| <i>nmb_crvs</i>    | the number of curves referred to by <i>first_curve</i> . |

## Returns

vector holding the unified curves.

## 28.22 Go::LoftVolumeCreator Namespace Reference

This namespace contains functions used to create lofted volumes.

## Functions

### 28.22.1 Detailed Description

This namespace contains functions used to create lofted volumes.

### 28.22.2 Function Documentation

#### 28.22.2.1 [SplineVolume](#)\* [Go::LoftVolumeCreator::loftNonrationalVolume](#) ( std::vector< shared\_ptr< [SplineSurface](#) > >::iterator *first\_surface*, std::vector< double >::iterator *first\_param*, int *nmb\_srfs* )

Create a lofting volume interpolating the input surfaces in the input parameters. For each parameter direction (u or v), the input surfaces are expected to have identical B-spline space. Either all or none of the surfaces are expected to be rational. In case the surfaces are rational, we also loft the denominator function. In this way, we might risk that the resulting volume has negative control points, this must be handled by the calling function. The returned lofted volume will non-rational if the surfaces are non-rational.

#### Parameters

|                      |                                                                              |
|----------------------|------------------------------------------------------------------------------|
| <i>first_surface</i> | iterator to first iso-surface in the lofted volume.                          |
| <i>first_param</i>   | iso parameter to corresponding surface referred to by <i>first_surface</i> . |
| <i>nmb_srfs</i>      | the number of surfaces referred to by <i>first_surface</i> .                 |

#### Returns

pointer to the created lofting volume.

#### 28.22.2.2 [SplineVolume](#)\* [Go::LoftVolumeCreator::loftRationalVolume](#) ( std::vector< shared\_ptr< [SplineSurface](#) > >::iterator *first\_surface*, std::vector< double >::iterator *first\_param*, int *nmb\_srfs* )

Create a lofting volume interpolating the input rational surfaces in the input parameters by Hermite interpolation, to ensure positive denominator function. For each parameter direction (u or v), the input surfaces are expected to have identical B-spline space. All of the surfaces are expected to be rational. The returned lofted volume will also be rational.

## Parameters

|                      |                                                                              |
|----------------------|------------------------------------------------------------------------------|
| <i>first_surface</i> | iterator to first iso-surface in the lofted volume.                          |
| <i>first_param</i>   | iso parameter to corresponding surface referred to by <i>first_surface</i> . |
| <i>nmb_srfs</i>      | the number of surfaces referred to by <i>first_surface</i> .                 |

## Returns

pointer to the created lofting volume.

**28.22.2.3** `SplineVolume* Go::LoftVolumeCreator::loftVolume ( std::vector< shared_ptr< SplineSurface > >::iterator first_surface, int nmb_srfs )`

Create a lofting volume based on the input surfaces. The surfaces are not changed during the lofting process. The surfaces must all lie in the same space

## Parameters

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <i>first_surface</i> | iterator to first iso-surface in the lofted volume.          |
| <i>nmb_srfs</i>      | the number of surfaces referred to by <i>first_surface</i> . |

## Returns

pointer to the created lofting volume.

**28.22.2.4** `SplineVolume* Go::LoftVolumeCreator::loftVolume ( std::vector< shared_ptr< SplineSurface > >::iterator first_surface, std::vector< double >::iterator first_param, int nmb_srfs )`

Create a lofting volume interpolating the input surfaces in the input parameters. The surfaces are not changed during the lofting process. The surfaces must all lie in the same space

## Parameters

|                      |                                                                              |
|----------------------|------------------------------------------------------------------------------|
| <i>first_surface</i> | iterator to first iso-surface in the lofted volume.                          |
| <i>first_param</i>   | iso parameter to corresponding surface referred to by <i>first_surface</i> . |
| <i>nmb_srfs</i>      | the number of surfaces referred to by <i>first_surface</i> .                 |

## Returns

pointer to the created lofting volume.

**28.22.2.5** `SplineVolume* Go::LoftVolumeCreator::loftVolumeFromUnifiedSurfaces ( std::vector< shared_ptr< SplineSurface > >::iterator first_surface, std::vector< double >::iterator first_param, int nmb_srfs )`

Create a lofting volume interpolating the input surfaces in the input parameters. For each parameter direction (u or v), the input surfaces are expected to have identical B-spline space. Either all or none of the surfaces are expected to be rational. The returned lofted volume will be rational if and only if the surfaces are rational.

## Parameters

|                      |                                                                              |
|----------------------|------------------------------------------------------------------------------|
| <i>first_surface</i> | iterator to first iso-surface in the lofted volume.                          |
| <i>first_param</i>   | iso parameter to corresponding surface referred to by <i>first_surface</i> . |
| <i>nmb_srfs</i>      | the number of surfaces referred to by <i>first_surface</i> .                 |

## Returns

pointer to the created lofting volume.

**28.22.2.6** void Go::LoftVolumeCreator::makeLoftParams ( std::vector< shared\_ptr< SplineSurface > >::const\_iterator *first\_surface*, int *nmb\_crvs*, double *param\_length*, std::vector< double > & *params* )

Calculate iso parameters for the input surfaces. The surfaces are expected to be ordered, i.e. corresponding to increasing iso parameters. Surfaces are given iso-parameters in the range 0.0 to *param\_length*. All the parameter differences between two neighbouring surfaces will be proportional to the quadratic mean of the distance between corresponding control points, i.e. if, for two surfaces  $S=first\_surface[i]$  and  $T=first\_surface[i+1]$ ,  $Q$  is the quadratic mean of the distance between corresponding control points of  $S$  and  $T$ , and  $P$  is the difference between the calculated parameter values for  $S$  and  $T$ , then the ratio  $Q/P$  is the same for all  $i$ .

## Parameters

|                      |                                                     |
|----------------------|-----------------------------------------------------|
| <i>first_surface</i> | iterator to first iso surface.                      |
| <i>nmb_crvs</i>      | the number of input surfaces.                       |
| <i>param_length</i>  | length of parameter domain.                         |
| <i>params</i>        | the computed iso parameters for the input surfaces. |

**28.22.2.7** std::vector<shared\_ptr<SplineSurface> > Go::LoftVolumeCreator::unifiedSurfacesCopy ( std::vector< shared\_ptr< SplineSurface > >::iterator *first\_surface*, int *nmb\_srfs* )

Create a vector of surfaces holding a copy of the input surfaces, but where the spline bases have been changed (reparametrized, knot inserted and order raised) so that the B-spline spaces in the  $u$ -direction for the new surfaces all are identical, same with  $v$ -direction, and where all surfaces are now rational if at least one of the input surfaces were rational. The input surfaces are not changed during the process. The surfaces must all lie in the same space.

## Parameters

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <i>first_surface</i> | iterator to first input surface.                             |
| <i>nmb_srfs</i>      | the number of surfaces referred to by <i>first_surface</i> . |

## Returns

vector holding the unified surfaces.

## 28.23 Go::LoopUtils Namespace Reference

## Functions

- void `representAsSurfaceCurves` (std::vector< shared\_ptr< [ParamCurve](#) > > &curves, shared\_ptr< [BoundedSurface](#) > surf, std::vector< shared\_ptr< [CurveOnSurface](#) > > &cvs\_on\_sf)
- bool `loopsCCW` (const std::vector< shared\_ptr< [Go::SplineCurve](#) > > &simple\_par\_loop, double space\_epsilon, double int\_tol)
- bool `paramsCCW` (const std::vector< shared\_ptr< [Go::CurveOnSurface](#) > > &loop, double space\_epsilon, double int\_tol)
- bool `loopsCCW` (const [CurveLoop](#) &loop, double int\_tol)
- bool `firstLoopInsideSecond` (const std::vector< shared\_ptr< [Go::CurveOnSurface](#) > > &first\_loop, const std::vector< shared\_ptr< [Go::CurveOnSurface](#) > > &second\_loop, double loop\_tol, double int\_tol)  
*Loops expected to be disjoint, except possibly share part of boundary.*
- bool `makeLoopCCW` (std::vector< shared\_ptr< [ParamCurve](#) > > &loop\_cvs, double tol)

### 28.23.1 Detailed Description

Functions for checking the orientation of loops (closed curves), and whether one loop on a surface encloses another.

### 28.23.2 Function Documentation

**28.23.2.1** bool `Go::LoopUtils::firstLoopInsideSecond` ( const std::vector< shared\_ptr< [Go::CurveOnSurface](#) > > & *first\_loop*, const std::vector< shared\_ptr< [Go::CurveOnSurface](#) > > & *second\_loop*, double *loop\_tol*, double *int\_tol* )

Loops expected to be disjoint, except possibly share part of boundary.

Test whether one loop lies entirely within another. This function does not work in the general case; it makes the assumption that the loops do NOT intersect each other transversally (their boundaries are allowed to tangentially touch though). The algorithm works by testing a single point on the first loop for being inside the second loop, so if the first loop lay partially inside, partially outside the second, the answer would be arbitrary.

#### Parameters

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>first_loop</i>  | the first loop                                                                                                        |
| <i>second_loop</i> | the second loop                                                                                                       |
| <i>loop_tol</i>    | the tolerance for defining coincidence between start/endpoints on the consecutive curve segments constituting a loop. |
| <i>int_tol</i>     | tolerance used for intersection calculations                                                                          |

#### Returns

'true' if 'first\_loop' was found to be located inside 'second\_loop' (given the assumptions above). 'false' otherwise.

**28.23.2.2** bool `Go::LoopUtils::loopsCCW` ( const std::vector< shared\_ptr< [Go::SplineCurve](#) > > & *simple\_par\_loop*, double *space\_epsilon*, double *int\_tol* )

Check if a closed 2D-loop is oriented counterclockwise or not.

## Parameters

|                        |                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------|
| <i>simple_par_loop</i> | a sequence of 2D curves that are joined start-to-end and that form a closed loop in the plane. |
| <i>int_tol</i>         | (geometric) tolerance used for internal computations (intersection detections)                 |

## Returns

'true' if the loop was found to be oriented CCW, otherwise 'false'.

**28.23.2.3** `bool Go::LoopUtils::loopsCCW ( const CurveLoop & loop, double int_tol )`

Check if a closed 2D-loop is oriented counterclockwise or not. The loop is given as a [CurveLoop](#).

**28.23.2.4** `bool Go::LoopUtils::makeLoopCCW ( std::vector< shared_ptr< ParamCurve > > & loop_cvs, double tol )`

Reorganize curves to create a ccw loop The curves are assumed to have correct sequence, but possible wrong parameter direction Return value: false = reorganization not possible

**28.23.2.5** `bool Go::LoopUtils::paramsCCW ( const std::vector< shared_ptr< Go::CurveOnSurface > > & loop, double space_epsilon, double int_tol )`

Check if a loop defined by [CurveOnSurface](#) s is oriented counterclockwise in the surface's parametric domain.

## Parameters

|                |                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>loop</i>    | a sequence of <a href="#">CurveOnSurface</a> s that are jointed start-to-end and that form a closed loop on the surface. |
| <i>int_tol</i> | (geometric) tolerance used for internal computations (intersection detections)                                           |

## Returns

'true' if the loop was found to be oriented CCW, otherwise 'false'.

**28.23.2.6** `void Go::LoopUtils::representAsSurfaceCurves ( std::vector< shared_ptr< ParamCurve > > & curves, shared_ptr< BoundedSurface > surf, std::vector< shared_ptr< CurveOnSurface > > & cvs_on_sf )`

Represent a vector of [ParamCurve](#) curves as a vector of [CurveOnSurface](#) curves The surface is given as additional input Note that the function throws if the surface information is inconsistent

## 28.24 Go::LRApproxApp Namespace Reference

### Functions

- void [pointCloud2Spline](#) (std::vector< double > &points, int dim, double domain[], double reduced\_domain[], double eps, int max\_iter, shared\_ptr< [LRSplineSurface](#) > &surf, double &maxdist, double &avdist, double &avdist\_out, int &nmb\_out)

## 28.30 Go::ModifySurf Namespace Reference

### Functions

- void replaceBoundary (shared\_ptr< SplineSurface > surf, shared\_ptr< SplineCurve > curve, int bd\_idx, double tol)
- bool enforceCoefCoLinearity (shared\_ptr< SplineSurface > sf1, int bd1, shared\_ptr< SplineSurface > sf2, int bd2, double tol, std::vector< int > & enumeration)
- bool enforceVxCoefCoLinearity (std::vector< shared\_ptr< SplineSurface > > &sfs, std::vector< int > &vx←\_enum, std::vector< std::pair< std::vector< int >, std::pair< int, int > > &coef\_cond, double tol)

### 28.30.1 Detailed Description

Functionality used to modify one or more spline surfaces with respect to given conditions

### 28.30.2 Function Documentation

**28.30.2.1** `bool Go::ModifySurf::enforceCoefCoLinearity ( shared_ptr< SplineSurface > sf1, int bd1, shared_ptr< SplineSurface > sf2, int bd2, double tol, std::vector< std::vector< int > > & enumeration )`

Enforce colinearity between coefficients at the common boundary between two spline surfaces. The two outer rows of coefficients are involved in the linearity constraints, but a few additional rows are modified for reasons of smoothness. All surface boundaries, except the affected one, are kept fixed.

**28.30.2.2** `bool Go::ModifySurf::enforceVxCoefCoLinearity ( std::vector< shared_ptr< SplineSurface > > & sfs, std::vector< int > & vx_enum, std::vector< std::pair< std::vector< int >, std::pair< int, int > > > & coef_cond, double tol )`

Enforce colinearity at vertices where 4 edge pairs meet. The two outer rows of coefficients around the vertex are involved in the linearity constraints, but a few additional rows are modified for reasons of smoothness.

**28.30.2.3** `void Go::ModifySurf::replaceBoundary ( shared_ptr< SplineSurface > surf, shared_ptr< SplineCurve > curve, int bd_idx, double tol )`

Replace one boundary curve of a [SplineSurface](#) Approximate the initial surface bd\_idx = 0: umin 1: umax 2: vmin

## 28.31 Go::OffsetSurfaceUtils Namespace Reference

### Functions

- [OffsetSurfaceStatus](#) `offsetSurfaceSet (const std::vector< shared_ptr< ParamSurface > > &param_sfs, double offset_dist, double epsgeo, shared_ptr< SplineSurface > &offset_sf)`

### 28.31.1 Function Documentation

**28.31.1.1** `OffsetSurfaceStatus Go::OffsetSurfaceUtils::offsetSurfaceSet ( const std::vector< shared_ptr< ParamSurface > > & param_sfs, double offset_dist, double epsgeo, shared_ptr< SplineSurface > & offset_sf )`

Compute the offset surface for a set of parametric surfaces (possibly 1 surface only). The surface set must have 4 corners.

#### Parameters

|                          |                                             |
|--------------------------|---------------------------------------------|
| <code>param_sfs</code>   | input parametric surfaces                   |
| <code>offset_dist</code> | distance for the offset surface.            |
| <code>epsgeo</code>      | geometric tolerance for the offset surface. |

**Returns**

status of the offset function. 0 => success, everything else a failure.

## 28.32 Go::OffsetUtils Namespace Reference

Related to the generation of cross tangent curves.

**Functions**

- void `blend_s1421` (`const SplineSurface *ps`, `double aoffset`, `int ider`, `const Point &epar`, `int &ilfs`, `int &ilft`, `std::vector< Point > &effpnt`, `std::vector< Point > &epnt`, `int *jstat`)

### 28.32.1 Detailed Description

Related to the generation of cross tangent curves.

### 28.32.2 Function Documentation

28.32.2.1 void Go::OffsetUtils::blend\_s1421 ( `const SplineSurface * ps`, `double aoffset`, `int ider`, `const Point & epar`, `int & ilfs`, `int & ilft`, `std::vector< Point > & effpnt`, `std::vector< Point > & epnt`, `int * jstat` )

## 28.33 Go::orientCurves Namespace Reference

Sorts and orients a set of curves.

**Functions**

- `template<class PtrToCurveType >`  
void `orientCurves` (`const std::vector< PtrToCurveType > &curves`, `std::vector< int > &permutation`, `std::vector< bool > &reversed`, `double neighbour_tol`, `bool assume_manifold=true`)

### 28.33.1 Detailed Description

Sorts and orients a set of curves.

### 28.33.2 Function Documentation

28.33.2.1 `template<class PtrToCurveType > void Go::orientCurves::orientCurves ( const std::vector< PtrToCurveType > & curves`, `std::vector< int > & permutation`, `std::vector< bool > & reversed`, `double neighbour_tol`, `bool assume_manifold = true` ) `[inline]`

This function sorts and orients a set of curves so that curves whose endpoints coincide will be ordered consecutively, and eventually 'reversed' so that startpoints meet endpoints. It is assumed that the set of curves given constitute one or several manifolds, ie., that there will not be cases where three or more endpoints meet at a common point (this would make the above mentioned ordering impossible).

## Parameters

|                        |                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>curves</i>          | a vector containing the set of (pointers to) curves to be analysed. It is expected that they constitute one or more 1-manifolds.                                                                                                                                                                                                                               |
| <i>permutation</i>     | upon return, this vector will contain a permutation of the indices to the input curves such that after this permutation, curves whose endpoints are connected will become 'consecutive'.                                                                                                                                                                       |
| <i>reversed</i>        | upon return, this vector, whose length will be equal to that of 'curves' and 'permutation', will contain bool values. If curve at position 'i' in the 'curves' vector needs to be reversed in order to connect startpoint-to-endpoint with its neighbours, then the corresponding value in 'reversed' will be 'true', and 'false' if no reversal is necessary. |
| <i>neighbour_tol</i>   | the tolerance used when checking for coincident points.                                                                                                                                                                                                                                                                                                        |
| <i>assume_manifold</i> | if the user specifies 'true', then the manifold property will be assumed, but will not be explicitly checked. If 'false' is specified, then the input <i>will</i> be checked for consistency with respect to this, and an exception will be cast if the manifold condition is violated.                                                                        |

## 28.34 Go::Path Namespace Reference

Functions related to sequence of edges.

### Functions

- `bool estimateHoleInfo (const std::vector< ftEdge * > &edges, Point &centre, Point &axis, double &radius, double &angle)`  
*sequence*
- `void classifyCorners (const std::vector< ftEdge * > &edges, double tol, std::vector< shared_ptr< Vertex > > &corner, std::vector< shared_ptr< Vertex > > &non_corner)`
- `std::vector< ftEdge * > identifyLoop (std::vector< ftEdge * > edges, shared_ptr< Vertex > vx)`
- `void closestPoint (std::vector< ftEdge * > edges, const Point &pt, int &clo_ind, double &clo_par, Point &clo_pt, double &clo_dist)`
- `void getEdgeCurves (std::vector< ftEdge * > &loop, std::vector< shared_ptr< ParamCurve > > &space_cvs, std::vector< Point > &joint_points, double eps, double tol, bool corner_in_Tjoint=true)`
- `std::vector< ftEdge * > edgeChain (ftEdge *edg, double angtol, shared_ptr< Vertex > &v1, shared_ptr< Vertex > &v2)`

### 28.34.1 Detailed Description

Functions related to sequence of edges.

### 28.34.2 Function Documentation

28.34.2.1 `void Go::Path::classifyCorners ( const std::vector< ftEdge * > &edges, double tol, std::vector< shared_ptr< Vertex > > &corner, std::vector< shared_ptr< Vertex > > &non_corner )`

Classify vertices in a path of edges as corner or non-corner depending on a given tolerance

28.34.2.2 void Go::Path::closestPoint ( std::vector< ftEdge \* > edges, const Point & pt, int & clo\_ind, double & clo\_par, Point & clo\_pt, double & clo\_dist )

28.34.2.3 std::vector<ftEdge\*> Go::Path::edgeChain ( ftEdge \* edg, double angtol, shared\_ptr< Vertex > & v1, shared\_ptr< Vertex > & v2 )

Extract edge chain with no joints between more than two edges or corners

28.34.2.4 bool Go::Path::estimateHoleInfo ( const std::vector< ftEdge \* > & edges, Point & centre, Point & axis, double & radius, double & angle )

sequence

Estimate mid point, normal and radius defined by an edge

28.34.2.5 void Go::Path::getEdgeCurves ( std::vector< ftEdge \* > & loop, std::vector< shared\_ptr< ParamCurve > > & space\_cvs, std::vector< Point > & joint\_points, double eps, double tol, bool corner\_in\_Tjoint = true )

Combine edges into 4 curves, preferably with splits in real corners

28.34.2.6 std::vector<ftEdge\*> Go::Path::identifyLoop ( std::vector< ftEdge \* > edges, shared\_ptr< Vertex > vx )

Identify a loops starting and ending in a given vertex in an ordered sequence of edges

## 28.35 Go::PointSetApp Namespace Reference

[Point](#) set and triangulation applications.

### Functions

- void [parameterizeTriang](#) (const double \*xyz\_points, int nmbp, const int \*triangles, int nmbt, std::vector< double > &uv\_pars)  
*Parameterize triangulated point set.*
- bool [recognizeBoundary](#) (shared\_ptr< ftPointSet > &triang, std::vector< int > &corner\_ix)  
*Service functionality for parameterizeTriang.*
- bool [recognizeCornerNodes](#) (const shared\_ptr< ftPointSet > &triang, const std::vector< int > &bd\_nodes, std::vector< int > &corner\_ix)

### 28.35.1 Detailed Description

[Point](#) set and triangulation applications.

### 28.35.2 Function Documentation

28.35.2.1 `void Go::PointSetApp::parameterizeTriang ( const double * xyz_points, int nmbp, const int * triangles, int nmbt, std::vector< double > & uv_pars )`

Parameterize triangulated point set.

28.35.2.2 `bool Go::PointSetApp::recognizeBoundary ( shared_ptr< ftPointSet > & triang, std::vector< int > & corner_ix )`

Service functionality for parameterizeTriang.

28.35.2.3 `bool Go::PointSetApp::recognizeCornerNodes ( const shared_ptr< ftPointSet > & triang, const std::vector< int > & bd_nodes, std::vector< int > & corner_ix )`

## 28.36 Go::qualityUtils Namespace Reference

### Functions

- [bool isSliverFace](#) (shared\_ptr< ParamSurface >, double thickness, double factor=2.0)
- [bool isSliverFace](#) (const SplineSurface &sf, double thickness, double factor=2.0)
- [bool isSliverFace](#) (const BoundedSurface &sf, double thickness, double factor=2.0)
- [bool isSliverFace2](#) (const BoundedSurface &sf, double thickness, double factor=2.0)
- [bool hasIndistinctKnots](#) (shared\_ptr< ParamSurface > surf, double tol, std::vector< shared\_ptr< ParamCurve > > &trim\_cv\_knots)
- [double estimateArea](#) (shared\_ptr< ParamSurface > surf)
- [double estimateLoopArea](#) (shared\_ptr< CurveLoop > loop)

### 28.36.1 Function Documentation

28.36.1.1 `double Go::qualityUtils::estimateArea ( shared_ptr< ParamSurface > surf )`

28.36.1.2 `double Go::qualityUtils::estimateLoopArea ( shared_ptr< CurveLoop > loop )`

28.36.1.3 `bool Go::qualityUtils::hasIndistinctKnots ( shared_ptr< ParamSurface > surf, double tol, std::vector< shared_ptr< ParamCurve > > & trim_cv_knots )`

28.36.1.4 `bool Go::qualityUtils::isSliverFace ( shared_ptr< ParamSurface >, double thickness, double factor = 2.0 )`

28.36.1.5 `bool Go::qualityUtils::isSliverFace ( const SplineSurface & sf, double thickness, double factor = 2.0 )`

28.36.1.6 `bool Go::qualityUtils::isSliverFace ( const BoundedSurface & sf, double thickness, double factor = 2.0 )`

28.36.1.7 `bool Go::qualityUtils::isSliverFace2 ( const BoundedSurface & sf, double thickness, double factor = 2.0 )`

## 28.37 Go::RegularizeUtils Namespace Reference

Utility functionality for [RegularizeFace](#) and [RegularizeFaceSet](#).

## Functions

- `std::vector< shared_ptr< ftSurface > > divideVertex` (`shared_ptr< ftSurface > face`, `shared_ptr< Vertex > vx`, `std::vector< shared_ptr< Vertex > > &cand_vx`, `ftEdge *cand_edge`, `std::vector< shared_ptr< Vertex > > &prio_vx`, `double epsge`, `double tol2`, `double angtol`, `double bend`, `std::vector< shared_ptr< Vertex > > &non_corner`, `const Point &centre`, `const Point &axis`, `bool strong=false`)

## 28.38 Go::Singular Namespace Reference

### Functions

- void `vanishingNormal` (shared\_ptr< ParamSurface > srf, double tol, std::vector< Point > &singular\_pts, std::vector< std::vector< Point > > &singular\_sequences)
- void `vanishingTangent` (shared\_ptr< ParamCurve > crv, double start, double end, double tol, std::vector< double > &singular\_pts, std::vector< std::vector< double > > &singular\_sequences)

### 28.38.1 Function Documentation

- 28.38.1.1 `void Go::Singular::vanishingNormal ( shared_ptr< ParamSurface > srf, double tol, std::vector< Point > & singular_pts, std::vector< std::vector< Point > > & singular_sequences )`
- 28.38.1.2 `void Go::Singular::vanishingTangent ( shared_ptr< ParamCurve > crv, double start, double end, double tol, std::vector< double > & singular_pts, std::vector< std::vector< double > > & singular_sequences )`

## 28.39 Go::SplineDebugUtils Namespace Reference

### Functions

- void `GO_API writeSpaceParamCurve` (const SplineCurve &pcurve, std::ostream &os, double z=0.0)
- void `GO_API writeSpaceParamCurve` (const Line &pline, std::ostream &os, double z=0.0)
- void `GO_API writeTrimmedInfo` (BoundedSurface &bd\_sf, std::ostream &os, double z=0.0)
- void `GO_API writeOuterBoundaryLoop` (ParamSurface &sf, std::ostream &os)
- void `GO_API objToFile` (GeomObject \*geom\_obj, char \*to\_file)
- void `GO_API objsToFile` (std::vector< shared\_ptr< GeomObject > > &geom\_objs, char \*to\_file)
- void `GO_API writeSISLFormat` (const SplineCurve &spline\_cv, std::ostream &os)
- void `GO_API writeCvsOnSf` (const std::vector< shared\_ptr< Go::ParamCurve > > &loop\_cvs, double epsgeo, std::ofstream &fileout)
- void `GO_API writeCvsOnSf` (const std::vector< shared\_ptr< Go::CurveOnSurface > > &loop\_cvs, double epsgeo, std::ofstream &fileout)

### 28.39.1 Detailed Description

For debugging. Writes a parameter curve in the xy-plane. Remove when GoViewer handles 2D curves.

### 28.39.2 Function Documentation

- 28.39.2.1 `void GO_API Go::SplineDebugUtils::objsToFile ( std::vector< shared_ptr< GeomObject > > & geom_objs, char * to_file )`

writes the geometric objects (with header) to the specified file name.

## Parameters

|                  |                                                     |
|------------------|-----------------------------------------------------|
| <i>geom_objs</i> | the objects to write to file.                       |
| <i>to_file</i>   | the file name to which the objects will be written. |

28.39.2.2 void GO\_API Go::SplineDebugUtils::objToFile ( *GeomObject* \* *geom\_obj*, char \* *to\_file* )

writes the geometric object (with header) to the specified file name.

## Parameters

|                 |                                                    |
|-----------------|----------------------------------------------------|
| <i>geom_obj</i> | the object to write to file.                       |
| <i>to_file</i>  | the file name to which the object will be written. |

28.39.2.3 void GO\_API Go::SplineDebugUtils::writeCvsOnSf ( const std::vector< shared\_ptr< Go::ParamCurve > > & *loop\_cvs*, double *epsgeo*, std::ofstream & *fileout* )

28.39.2.4 void GO\_API Go::SplineDebugUtils::writeCvsOnSf ( const std::vector< shared\_ptr< Go::CurveOnSurface > > & *loop\_cvs*, double *epsgeo*, std::ofstream & *fileout* )

28.39.2.5 void GO\_API Go::SplineDebugUtils::writeOuterBoundaryLoop ( *ParamSurface* & *sf*, std::ostream & *os* )

28.39.2.6 void GO\_API Go::SplineDebugUtils::writeSISLFormat ( const *SplineCurve* & *spline\_cv*, std::ostream & *os* )

Write a [SplineCurve](#) to a stream using the SISL file format (not the [Go](#) format).

## Parameters

|                  |                                                                 |
|------------------|-----------------------------------------------------------------|
| <i>spline_cv</i> | the curve to write to a stream                                  |
| <i>os</i>        | the stream to which the curve will be written (in SISL format)x |

28.39.2.7 void GO\_API Go::SplineDebugUtils::writeSpaceParamCurve ( const *SplineCurve* & *pcurve*, std::ostream & *os*, double *z = 0.0* )

For debugging. Writes a parameter curve (2D) in the xy-plane, for a given z-value. It will be written (with header) to the specified stream as a 3D curve.

## Parameters

|               |                                                    |
|---------------|----------------------------------------------------|
| <i>pcurve</i> | the parameter curve we want to write as a 3D curve |
| <i>os</i>     | the stream to which we want to write the 3D curve  |
| <i>z</i>      | the constant z-value for the generated curve       |

28.39.2.8 void **GO\_API** Go::SplineDebugUtils::writeSpaceParamCurve ( const Line & *pline*, std::ostream & *os*, double *z* = 0.0 )

28.39.2.9 void **GO\_API** Go::SplineDebugUtils::writeTrimmedInfo ( BoundedSurface & *bd\_sf*, std::ostream & *os*, double *z* = 0.0 )

Write the parameter curve (if existing) and the space curve (if existing) to the output stream. Both curves are written as 3D curves extending 2D curves with the given z-value.

### 28.40.1 Detailed Description

Utility functionality related to spline curves and surfaces or functions operating on spline curves and surfaces

### 28.40.2 Function Documentation

28.40.2.1 int **GO\_API** Go::SplineUtils::closest\_in\_array ( const double \* *pt*, const double \* *array*, int *n*, int *dim* )

Find the point in an array closest to the given base point (measured in the usual, Euclidean distance)

## Parameters

|              |                                              |
|--------------|----------------------------------------------|
| <i>pt</i>    | pointer to the base point (of dimension 'n') |
| <i>array</i> | pointer to the array in which we will search |
| <i>n</i>     | number of elements in the array              |
| <i>dim</i>   | dimension of the elements/base point         |

28.40.2.2 **double GO\_API Go::SplineUtils::closest\_on\_line\_segment ( const Vector3D & *pt*, const Vector3D & *beg*, const Vector3D & *end* )**

Find the closest point on a line segment to a given point.

## Parameters

|            |                                                                           |
|------------|---------------------------------------------------------------------------|
| <i>pt</i>  | the point for which we want to find the closest point on the line segment |
| <i>beg</i> | the start point of the line segment                                       |
| <i>end</i> | the end point of the line segment                                         |

## Returns

the barycentric coordinate of the closest point on the line segment (number between 0 and 1, where 0 is the start point and 1 is the end point)

28.40.2.3 **void GO\_API Go::SplineUtils::closest\_on\_rectgrid ( const double \* *pt*, const double \* *array*, int *m*, int *n*, double & *clo\_u*, double & *clo\_v* )**

Find an approximate closest point on a rectangular grid of 3-dimensional points. The method used is to 'triangulate' the grid, and locate the closest point on this triangulation. We imagine that the point grid is uniformly parametrized from 0 to *m*-1 along each row and from 0 to *n*-1 along each column, and we refer to these parameters as 'u' and 'v'.

## Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>pt</i>                 | the point we want to search the closest point for                                                      |
| <i>array</i>              | pointer to the array of 3D-points; coordinates should be stored consecutively in a row-wise fashion.   |
| <i>m</i>                  | number of columns in the point array                                                                   |
| <i>n</i>                  | number of rows in the point array                                                                      |
| <i>clo</i> ↔<br><i>_u</i> | upon function return; the u-parameter of the closest point, using the parametrization explained above. |
| <i>clo</i> ↔<br><i>_v</i> | upon function return; the v-parameter of the closest point, using the parametrization explained above. |

28.40.2.4 **void GO\_API Go::SplineUtils::closest\_on\_rectgrid ( const double \* *pt*, const double \* *array*, int *u\_min*, int *u\_max*, int *v\_min*, int *v\_max*, int *nmb\_coefs\_u*, double & *clo\_u*, double & *clo\_v* )**

Find an approximate closest point on a sub-grid of a rectangular grid of 3-dimensional points. The method used is to 'triangulate' the grid, and locate the closest point on this triangulation. We imagine that the parametrization of the sub-grid is from 'u\_min' to 'u\_max' along each row and from 'v\_min' to 'v\_max' along each column.

## Parameters

|                               |                                                                                                                                               |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pt</i>                     | the point we want to search the closest point for                                                                                             |
| <i>array</i>                  | pointer to the array of 3D-points; coordinates should be stored consecutively in a row-wise fashion.                                          |
| <i>u_min</i>                  | lowest column index of the subgrid we want to search                                                                                          |
| <i>u_max</i>                  | highest column index of the subgrid we want to search                                                                                         |
| <i>v_min</i>                  | lowest row index of the subgrid we want to search                                                                                             |
| <i>v_max</i>                  | highest row index of the subgrid we want to search                                                                                            |
| <i>nmb_coefs</i><br><i>_u</i> | total number of columns in the complete grid (necessary to know in order to determine how far to jump to get to the next row in the subgrid). |
| <i>clo_u</i>                  | upon function return; the u-parameter of the closest point, using the parametrization explained above.                                        |
| <i>clo_v</i>                  | upon function return; the v-parameter of the closest point, using the parametrization explained above.                                        |

28.40.2.5 **Vector3D GO\_API Go::SplineUtils::closest\_on\_triangle ( const Vector3D & *pt*, const Vector3D *tri*[3], double & *clo\_dist2* )**

Find the closest point on a triangle, in barycentric coordinates.

## Parameters

|                  |                                                                                |
|------------------|--------------------------------------------------------------------------------|
| <i>pt</i>        | the point for which we want to find the closest point on the triangle          |
| <i>tri</i>       | the triangle, specified by its three corners                                   |
| <i>clo_dist2</i> | the squared Euclidean distance from 'pt' to the closest point in the triangle. |

## Returns

the barycentric coordinates of the closest point on the triangle

28.40.2.6 **void GO\_API Go::SplineUtils::curve\_ratder ( double const *eder*[], int *idim*, int *ider*, double *gder*[] )**

This function takes as input the position and a certain number of derivatives in homogenous space of a point on a rational curve. It outputs the position and derivatives of this point in non-homogenous ("ordinary") space. (Corresponds to *s6ratder* in SISL)

## Parameters

|             |                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>eder</i> | pointer to the array where the point's position and derivatives in homogenous coordinates (input) are consecutively stored |
| <i>idim</i> | the dimension of the non-homogenous space                                                                                  |
| <i>ider</i> | the number of derivatives sought (0 means that we only want to convert the <i>position</i> to non-homogenous coordinates). |
| <i>gder</i> | pointer to the array where the result will be written (in same order as ' <i>eder</i> ').                                  |

28.40.2.7 void GO\_API Go::SplineUtils::extractBezierCoefs ( const double \* *coefs*, const int *num\_coefs\_u*, const int *num\_coefs\_v*, const int *ind\_u\_min*, const int *ind\_v\_min*, const std::vector< double > & *transf\_mat\_u*, const std::vector< double > & *transf\_mat\_v*, std::vector< double > & *bezier\_coefs* )

Assuming surface is bi-cubic (i.e. order 4). Extract the bezier patch corr to the domain (knots\_u[*ind\_u\_min*], knots\_u[*ind\_u\_min*+1])x(knots\_v[*ind\_v\_min*], knots\_v[*ind\_v\_min*+1]).

#### Parameters

|                  |                                              |
|------------------|----------------------------------------------|
| <i>ind_u_min</i> | Basis pointer corresponding to <i>umin</i> . |
| <i>ind_v_min</i> | Basis pointer corresponding to <i>vmin</i> . |

28.40.2.8 shared\_ptr<SplineSurface> GO\_API Go::SplineUtils::insertKnots ( const Go::SplineSurface & *spline\_sf*, const std::vector< double > *new\_knots\_u*, const std::vector< double > *new\_knots\_v* )

28.40.2.9 void GO\_API Go::SplineUtils::make\_coef\_array\_from\_rational\_coefs ( const double \* *rationals*, double \* *coefs*, int *num\_coefs*, int *dim* )

convert an array of rational coefficients to an array of nonrational coefficients

#### Parameters

|                  |                                                                           |
|------------------|---------------------------------------------------------------------------|
| <i>rationals</i> | pointer to the array of rational coefficients                             |
| <i>coefs</i>     | pointer to the array where the nonrational coefficients are to be written |
| <i>num_coefs</i> | total number of coefficients                                              |
| <i>dim</i>       | dimension of coefficients (not counting the rational component).          |

28.40.2.10 void GO\_API Go::SplineUtils::osloalg ( int *ij*, int *imy*, int *ik*, int *in*, int \* *jpl*, int \* *jfi*, int \* *jla*, const double \* *et*, const double \* *etau*, double \* *galfa* )

Corresponds to s1701 in SISL This function computes in a compact format a line in the discrete B-spline matrix converting between an original basis "etau" and a new basis "et".

#### Parameters

|              |                                                                                                                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ij</i>    | The index of the new vertice                                                                                                                                                                                                                                          |
| <i>imy</i>   | An index on etau, where the input value are to be etau( <i>imy</i> ) <= et( <i>ij</i> ) < etau( <i>imy</i> + 1).                                                                                                                                                      |
| <i>ik</i>    | The order of the B-spline.                                                                                                                                                                                                                                            |
| <i>in</i>    | The number of the original vertices.                                                                                                                                                                                                                                  |
| <i>et</i>    | The new knot vector.                                                                                                                                                                                                                                                  |
| <i>etau</i>  | The old knot vector.                                                                                                                                                                                                                                                  |
| <i>et</i>    | An array ep( <i>ik</i> ) to local use. Such that we do not need to allocate the array locally after each call.                                                                                                                                                        |
| <i>jpl</i>   | The negativ difference between the index in galfa and the real knot inserten matrix.                                                                                                                                                                                  |
| <i>jfi</i>   | The index of the first element in the line j in the the real knot inserten matrix whice is not zero. The element with the index ( <i>jfi</i> + <i>jpl</i> ) in galfa is the same as the element with index <i>jfi</i> in the real line j in the knot inserten matrix. |
| <i>jla</i>   | The index of the last element in the line j in the real knot inserten matrix whice is not zero. The element with the index ( <i>jla</i> + <i>jpl</i> ) in galfa is the same as the element with index <i>jla</i> in the real line j in the knot inserten matrix.      |
| <i>galfa</i> | A compressed line in the knot inserten matrix.                                                                                                                                                                                                                        |

28.40.2.11 void **GO\_API** Go::SplineUtils::refinedBezierCoefsCubic ( Go::SplineSurface & *spline\_sf*, int *ind\_u\_min*, int *ind\_v\_min*, std::vector< double > & *bez\_coefs* )

Method expecting bi-cubic input.

28.40.2.12 shared\_ptr<SplineSurface> **GO\_API** Go::SplineUtils::refineToBezier ( const Go::SplineSurface & *spline\_sf* )

28.40.2.13 void **GO\_API** Go::SplineUtils::refmatrix ( const double \* *et*, int *im*, int *ik*, const double \* *etau*, int *in*, double \* *ea*, int \* *nfirst*, int \* *nlast* )

Corresponds to sh1922 in SISL. Computes the B-spline refinement transformation matrix from the spline space generated by the knot vector etau to the refined spline space generated by the refined knot vector et.

#### Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>et</i>     | Real array of length (im+ik) containing the refined knot vector.                                                                                                                                                                                                                                                                                                |
| <i>im</i>     | The dimension of the spline space corresponding to et.                                                                                                                                                                                                                                                                                                          |
| <i>ik</i>     | The order of the spline space.                                                                                                                                                                                                                                                                                                                                  |
| <i>etau</i>   | Real array of length (in+ik) containing the original knot vector.                                                                                                                                                                                                                                                                                               |
| <i>in</i>     | The dimension of the spline space corresponding to etau.                                                                                                                                                                                                                                                                                                        |
| <i>ea</i>     | Real array of dimension (im*ik) containing the B-spline refinement matrix from the knot vector etau to the knot vector et. This matrix has dimension im*in but since at most ik entries are nonzero in each row, it can be stored in a im*ik array together with two integer arrays indicating the position of the first and last nonzero elements in each row. |
| <i>nfirst</i> | Integer array of dimension (im) containing pointers to the first nonzero element of each row of the B-spline refinement matrix from etau to et.                                                                                                                                                                                                                 |
| <i>nlast</i>  | Integer array of dimension (im) containing pointers to the last nonzero element of each row of the B-spline refinement matrix from etau to et.                                                                                                                                                                                                                  |

28.40.2.14 void **GO\_API** Go::SplineUtils::splineToBezierTransfMat ( const double \* *knots*, std::vector< double > & *transf\_mat* )

Assuming basis is cubic (i.e. order 4). Create the transformation matrix which extract the bezier coefs for the interval (knots[3], knots[4]).

28.40.2.15 void **GO\_API** Go::SplineUtils::surface\_ratder ( double const *eder*[], int *idim*, int *ider*, double *gder*[]) )

This function takes as input the position and a certain number of derivatives in homogenous space of a point on a rational surface. It outputs the position and derivatives of this point in non-homogenous ("ordinary") space. (Corresponds to s6strider in SISL)

## Parameters

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>eder</i> | pointer to double array of dimension $[(ider+1)*(ider+2)*(idim+1)/2]$ containing the position and the derivative vectors of the homogeneous surface at the point with parameter value (epar[0],epar[1]). (idim+1 is the number of components of each B-spline coefficient, i.e. the dimension of the homogeneous space in which the surface lies.) These vectors are stored in the following order: First the idim+1 components of the position vector, then the idim+1 components of the D(1,0) vector, then the idim+1 components of the D(0,1) vector, then the idim+1 components of the D(2,0) vector, followed by D(1,1), D(0,2) and so on up to the idim+1 components of the D(0,ider). |
| <i>idim</i> | The dimension of the non homogenous space                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>ider</i> | The number of input derivatives with respect to both parameter directions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>gder</i> | pointer to the array where the result will be written (in same order as 'eder').                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

28.40.2.16 void **GO\_API** Go::SplineUtils::transpose\_array ( int *dim*, int *m*, int *n*, double \* *array\_start* )

Utility functionality related to spline curves and surfaces or functions operating on spline curves and surfaces Transpose an (m x n) matrix of dim-dimensional points stored as an array in row-major order (i.e. all elements of a single row are stored together).

## Parameters

|                    |                                                      |
|--------------------|------------------------------------------------------|
| <i>dim</i>         | the dimension of each of the points in the array     |
| <i>m</i>           | number of lines in the matrix                        |
| <i>n</i>           | number of columns in the matrix                      |
| <i>array_start</i> | pointer to the start of array where matrix is stored |

## 28.41 Go::SplitModelUtils Namespace Reference

Utility functionality for splitting of surface models.

### Functions

- void [splitInFreeCorners](#) (shared\_ptr< [SurfaceModel](#) > *sfmodel*, const [Point](#) &*pnt*, const [Point](#) &*axis*)
- void [splitInNonCorners](#) (shared\_ptr< [SurfaceModel](#) > *sfmodel*, const [Point](#) &*pnt*, const [Point](#) &*axis*)
- void [splitInOuterVertices](#) (shared\_ptr< [SurfaceModel](#) > *sfmodel*, shared\_ptr< [ftSurface](#) > *face*, const [Point](#) &*pnt*, const [Point](#) &*axis*)

#### 28.41.1 Detailed Description

Utility functionality for splitting of surface models.

#### 28.41.2 Function Documentation

28.41.2.1 void Go::SplitModelUtils::splitInFreeCorners ( shared\_ptr< [SurfaceModel](#) > *sfmodel*, const [Point](#) & *pnt*, const [Point](#) & *axis* )

The model is split from corners vertices belonging only to one face towards the axis defined by pnt and axis

28.41.2.2 void Go::SplitModelUtils::splitInNonCorners ( shared\_ptr< SurfaceModel > *sfmodel*, const Point & *pnt*, const Point & *axis* )

The model is split from vertices that do not constitute a corner for the current face towards the axis defined by *pnt* and *axis*

28.41.2.3 void Go::SplitModelUtils::splitInOuterVertices ( shared\_ptr< SurfaceModel > *sfmodel*, shared\_ptr< ftSurface > *face*, const Point & *pnt*, const Point & *axis* )

The model is split from vertices in outer loops towards the axis defined by *pnt* and *axis* or towards vertices in inner loops

## 28.42 Go::SurfaceCreators Namespace Reference

### Functions

- shared\_ptr< SplineSurface > createSmoothTransition (const std::vector< shared\_ptr< const ParamSurface > > &surfs, const std::vector< shared\_ptr< const CurveOnSurface > > &int\_cvs, double dist\_0, double dist\_1, double epsge, std::vector< shared\_ptr< SplineCurve > > &trim\_crvs)
- shared\_ptr< SplineSurface > mult1DSurfaces (const SplineSurface &sf1, const SplineSurface &sf2)
- shared\_ptr< SplineSurface > mult1DBezierPatches (const SplineSurface &patch1, const SplineSurface &patch2)
- shared\_ptr< Go::SplineSurface > mergeRationalParts (const Go::SplineSurface &nom\_sf, const Go::SplineSurface &den\_sf, bool weights\_in\_first=false)
- shared\_ptr< Go::SplineSurface > insertParamDomain (const Go::SplineSurface &sf\_1d)
- std::vector< shared\_ptr< Go::SplineSurface > > separateRationalParts (const Go::SplineSurface &sf)

### 28.42.1 Detailed Description

Various functions for generating [SplineSurface](#) s by approximation, blending, etc.

### 28.42.2 Function Documentation

28.42.2.1 shared\_ptr<SplineSurface> Go::SurfaceCreators::createSmoothTransition ( const std::vector< shared\_ptr< const ParamSurface > > & *surfs*, const std::vector< shared\_ptr< const CurveOnSurface > > & *int\_cvs*, double *dist\_0*, double *dist\_1*, double *epsge*, std::vector< shared\_ptr< SplineCurve > > & *trim\_crvs* )

Given input of two parametric surfaces, which intersect along an edge, create a smooth surface by moving boundary of *surfs* to inner part of current *surfs*. Normals of input *surfs* are assumed to be consistent.

#### Parameters

|                  |                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>surfs</i>     | the input surfaces, size of vector is 2.                                                                                                 |
| <i>int_cvs</i>   | intersection curves between the two surfaces. Vector has size 2. Both parameter curves should exist, the space curve should be the same. |
| <i>dist_0</i>    | the offset space distance in <i>surfs</i> [0].                                                                                           |
| <i>dist_1</i>    | the offset space distance in <i>surfs</i> [1].                                                                                           |
| <i>epsge</i>     | the geometrical tolerance when offsetting.                                                                                               |
| <i>trim_crvs</i> | the offset trim curves: <i>par_cv0</i> , <i>space_cv0</i> , <i>par_cv1</i> , <i>space_cv1</i> .                                          |

28.42.2.2 `shared_ptr<Go::SplineSurface> Go::SurfaceCreators::insertParamDomain ( const Go::SplineSurface & sf_1d )`

Given input of 1d-sf, return the 3d visualization (u, v, f(u, v)).

#### Parameters

|                    |                        |
|--------------------|------------------------|
| <code>sf_1d</code> | 1-dimensional surface. |
|--------------------|------------------------|

#### Returns

the 3-dimensional surface.

28.42.2.3 `shared_ptr<Go::SplineSurface> Go::SurfaceCreators::mergeRationalParts ( const Go::SplineSurface & nom_sf, const Go::SplineSurface & den_sf, bool weights_in_first = false )`

Return the rational surface 'nom\_sf/den\_sf'.

#### Parameters

|                               |                                                                                                                   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>nom_sf</code>           | the nominator surface.                                                                                            |
| <code>den_sf</code>           | the denominator surface.                                                                                          |
| <code>weights_in_first</code> | true if the coefficients of the nom_sf have been multiplied by the corresponding rational coefficients in den_sf. |

#### Returns

the rational surface.

28.42.2.4 `shared_ptr<SplineSurface> Go::SurfaceCreators::mult1DBezierPatches ( const SplineSurface & patch1, const SplineSurface & patch2 )`

Return the product of the two Bezier patches. Expecting them to be non-rational.

#### Parameters

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| <code>patch1</code> | <a href="#">SplineSurface</a> of Bezier type (i.e. no inner knots). |
| <code>patch2</code> | <a href="#">SplineSurface</a> of Bezier type (i.e. no inner knots). |

#### Returns

the surface product.

28.42.2.5 `shared_ptr<SplineSurface> Go::SurfaceCreators::mult1DSurfaces ( const SplineSurface & sf1, const SplineSurface & sf2 )`

Return the product of the two spline surfaces. Expecting them to be non-rational.

## Parameters

|            |                     |
|------------|---------------------|
| <i>sf1</i> | the first surface.  |
| <i>sf2</i> | the second surface. |

## Returns

the surface product.

28.42.2.6 `std::vector<shared_ptr<Go::SplineSurface> > Go::SurfaceCreators::separateRationalParts ( const Go::SplineSurface & sf )`

Assuming the *sf* is rational, separate the geometric space from the homogenous.

## Parameters

|           |                           |
|-----------|---------------------------|
| <i>sf</i> | the input spline surface. |
|-----------|---------------------------|

## Returns

the non-rational parts of *sf*.

## 28.43 Go::SurfaceInterpolator Namespace Reference

Functionality for creating interpolating surfaces.

### Functions

- `SplineSurface * regularInterpolation (const BsplineBasis &basis_u, const BsplineBasis &basis_v, std::vector< double > &par_u, std::vector< double > &par_v, std::vector< double > &points, int dimension, bool rational, std::vector< double > &weights)`

#### 28.43.1 Detailed Description

Functionality for creating interpolating surfaces.

#### 28.43.2 Function Documentation

28.43.2.1 `SplineSurface* Go::SurfaceInterpolator::regularInterpolation ( const BsplineBasis & basis_u, const BsplineBasis & basis_v, std::vector< double > & par_u, std::vector< double > & par_v, std::vector< double > & points, int dimension, bool rational, std::vector< double > & weights )`

Interpolate a set of regular, parameterized interpolation points. The parameterization is assumed to correspond to the given B-spline bases (select interpolation points in the Greville points). The function throws if the input parameters are inconsistent

## 28.44 Go::SurfaceModelUtils Namespace Reference

Utility functionality for splitting of surface models.

### Functions

- `std::vector< shared_ptr< ParamSurface > >` `checkClosedFaces` (`shared_ptr< ParamSurface >` `surface`, `double tol`)

#### 28.44.1 Detailed Description

Utility functionality for splitting of surface models.

#### 28.44.2 Function Documentation

28.44.2.1 `std::vector<shared_ptr<ParamSurface>>` `Go::SurfaceModelUtils::checkClosedFaces` ( `shared_ptr< ParamSurface >` `surface`, `double tol` )

## 28.45 Go::SurfaceOnVolumeTools Namespace Reference

### Functions

- `CurveLoop` `getOuterBoundaryLoop` (`shared_ptr< SurfaceOnVolume >` `sf`, `double eps`)

#### 28.45.1 Detailed Description

This namespace contains functions used to fetch boundary curves from surface on volumes

#### 28.45.2 Function Documentation

28.45.2.1 `CurveLoop` `Go::SurfaceOnVolumeTools::getOuterBoundaryLoop` ( `shared_ptr< SurfaceOnVolume >` `sf`, `double eps` )

Fetch the outer loop of the surface. This function is implemented outside of `SurfaceOnVolume` to allow the resulting curves to be of type `CurveOnSurface` and possess all the information related to this curve type.

## 28.46 Go::SurfaceTools Namespace Reference

Free functions operating on parametric surfaces.

## Functions

- [CurveLoop](#) [outerBoundarySfLoop](#) (shared\_ptr< [ParamSurface](#) > surf, double degenerate\_epsilon)
 

*Fetch the outer boundary loop of a parametric surface.*
- std::vector< [CurveLoop](#) > [allBoundarySfLoops](#) (shared\_ptr< [ParamSurface](#) > surf, double degenerate\_epsilon)
 

*Fetch all boundary loops of a parametric surface.*
- std::vector< [CurveLoop](#) > [absolutelyAllBoundarySfLoops](#) (shared\_ptr< [ParamSurface](#) > surf, double degenerate\_epsilon)
- void [iterateCornerPos](#) ([Point](#) &vertex, std::vector< std::pair< shared\_ptr< [ParamSurface](#) >, [Point](#) > > sfs, double tol)
- bool [cornerToCornerSfs](#) (shared\_ptr< [ParamSurface](#) > sf1, shared\_ptr< [CurveOnSurface](#) > sf\_cv1, shared\_ptr< [ParamSurface](#) > sf2, shared\_ptr< [CurveOnSurface](#) > sf\_cv2, double tol)
- bool [getSfAdjacencyInfo](#) (shared\_ptr< [ParamSurface](#) > sf1, shared\_ptr< [CurveOnSurface](#) > sf\_cv1, shared\_ptr< [ParamSurface](#) > sf2, shared\_ptr< [CurveOnSurface](#) > sf\_cv2, double tol, int &bd1, int &bd2, bool &same\_orient)
- bool [getCorrCoefEnum](#) (shared\_ptr< [SplineSurface](#) > sf1, shared\_ptr< [SplineSurface](#) > sf2, int bd1, int bd2, bool same\_orient, std::vector< std::pair< int, int > > &enumeration)
- bool [getCoefEnumeration](#) (shared\_ptr< [SplineSurface](#) > sf, int bd, std::vector< int > &enumeration)
- bool [getCoefEnumeration](#) (shared\_ptr< [SplineSurface](#) > sf, int bd, std::vector< int > &enumeration\_bd, std::vector< int > &enumeration\_bd2)
- bool [getCornerCoefEnum](#) (shared\_ptr< [SplineSurface](#) > sf, int bd1, int bd2, int &enumeration)
- int [checkCoefCoLinearity](#) (shared\_ptr< [SplineSurface](#) > sf1, shared\_ptr< [SplineSurface](#) > sf2, int bd1, int bd2, bool same\_orient, double tol, double ang\_tol, std::vector< std::vector< int > > &enumeration)
- void [surface\\_seedfind](#) (const [Point](#) &pt, const [ParamSurface](#) &sf, const [RectDomain](#) \*rd, double &u, double &v)
- void [parameterizeByBaseSurf](#) (const [ParamSurface](#) &sf, const std::vector< double > &points, std::vector< double > &parvals)
- double [estimateTangentLength](#) ([SplineSurface](#) \*surf, int pardir, bool at\_start)
- void [GO\\_API checkSurfaceClosed](#) (const [Go::ParamSurface](#) &sf, bool &closed\_dir\_u, bool &closed\_dir\_v, double closed\_tol=1e-06)
- void [GO\\_API surfaceClosed](#) (const [Go::SplineSurface](#) &sf, bool &closed\_dir\_u, bool &closed\_dir\_v, double closed\_tol=1e-06)
- [Point](#) [getParEpsilon](#) (const [ParamSurface](#) &sf, double epsgeo)

### 28.46.1 Detailed Description

Free functions operating on parametric surfaces.

### 28.46.2 Function Documentation

28.46.2.1 `std::vector<CurveLoop> Go::SurfaceTools::absolutelyAllBoundarySfLoops ( shared_ptr< ParamSurface > surf, double degenerate_epsilon )`

Fetch all boundary loops of a parametric surface including degenerate curves

28.46.2.2 `std::vector<CurveLoop> Go::SurfaceTools::allBoundarySfLoops ( shared_ptr< ParamSurface > surf, double degenerate_epsilon )`

Fetch all boundary loops of a parametric surface.

28.46.2.3 `int Go::SurfaceTools::checkCoefCoLinearity ( shared_ptr< SplineSurface > sf1, shared_ptr< SplineSurface > sf2, int bd1, int bd2, bool same_orient, double tol, double ang_tol, std::vector< std::vector< int > > & enumeration )`

Find coefficient enumeration of possible colinear coefficients at a common edge and check whether the coefficients are indeed colinear (return value: 0 = no correspondance, 1 = almost colinear, 2 = conditions defined)

28.46.2.4 `void GO_API Go::SurfaceTools::checkSurfaceClosed ( const Go::ParamSurface & sf, bool & closed_dir_u, bool & closed_dir_v, double closed_tol = 1e-06 )`

Check if the surface is closed in one or both paramater directions

28.46.2.5 `bool Go::SurfaceTools::cornerToCornerSfs ( shared_ptr< ParamSurface > sf1, shared_ptr< CurveOnSurface > sf_cv1, shared_ptr< ParamSurface > sf2, shared_ptr< CurveOnSurface > sf_cv2, double tol )`

Check if two neighbouring surfaces in a surface set have a corner-to-corner configuration, i.e. no T-joints

#### Parameters

|               |                                                                                        |
|---------------|----------------------------------------------------------------------------------------|
| <i>sf1</i>    | one surface                                                                            |
| <i>sf_cv1</i> | the boundary curve/trimming curve corresponding to sf1 at the boundary common with sf2 |
| <i>sf2</i>    | the other surface                                                                      |
| <i>sf_cv2</i> | the boundary curve/trimming curve corresponding to sf2 at the boundary common with sf1 |
| <i>return</i> | parameter true of the configuration is corner-to-corner                                |

28.46.2.6 `double Go::SurfaceTools::estimateTangentLength ( SplineSurface * surf, int paddir, bool at_start )`

Estimate the average length of the cross tangent of a spline surface at a given boundary

#### Parameters

|                 |                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>surf</i>     | the surface                                                                                                             |
| <i>paddir</i>   | = 1 : the cross tangent curve has constant u-parameter<br>paddir = 0 : the cross tangent curve has constant v-parameter |
| <i>at_start</i> | the cross tangent curve is evaluated at the start of the parameter domain in the given parameter direction              |

28.46.2.7 `bool Go::SurfaceTools::getCoefEnumeration ( shared_ptr< SplineSurface > sf, int bd, std::vector< int > & enumeration )`

Fetch the local enumeration of the surface coefficients along a specified boundary (bd=0 - umin, bd=1 - umax, bd=2 - vmin, bd=3 - vmax)

28.46.2.8 **bool** Go::SurfaceTools::getCoefEnumeration ( *shared\_ptr*< **SplineSurface** > *sf*, *int* *bd*, *std::vector*< *int* > & *enumeration\_bd*, *std::vector*< *int* > & *enumeration\_bd2* )

Return both the boundary coefficients as well as coefficient row number 2 when counting from the edge.

28.46.2.9 **bool** Go::SurfaceTools::getCornerCoefEnum ( *shared\_ptr*< **SplineSurface** > *sf*, *int* *bd1*, *int* *bd2*, *int* & *enumeration* )

Fetch the coefficient enumeration of the corner of a spline surface specified by the two boundaries meeting in this corner

28.46.2.10 **bool** Go::SurfaceTools::getCorrCoefEnum ( *shared\_ptr*< **SplineSurface** > *sf1*, *shared\_ptr*< **SplineSurface** > *sf2*, *int* *bd1*, *int* *bd2*, **bool** *same\_orient*, *std::vector*< *std::pair*< *int*, *int* > > & *enumeration* )

Given two spline surfaces and information about a common boundary between these surfaces, compute the enumeration of corresponding coefficients along this boundary provided that the surfaces have got the same spline space along the boundary

#### Parameters

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>sf1</i>         | first surface                                                                                                                |
| <i>sf2</i>         | second surface                                                                                                               |
| <i>bd1</i>         | boundary curve of first surface which follows the common boundary, -1=no such boundary curve, 0=umin, 1=umax, 2=vmin, 3=vmax |
| <i>bd2</i>         | boundary curve of second surface which follows the common boundary                                                           |
| <i>same_orient</i> | whether or not the surface boundaries have got the same orientation along the common boundary                                |
| <i>return</i>      | value whether or not the surfaces have got the same spline space                                                             |
| <i>enumeration</i> | pairwise enumeration of the corresponding coefficients in the two surfaces                                                   |

28.46.2.11 **Point** Go::SurfaceTools::getParEpsilon ( **const** **ParamSurface** & *sf*, **double** *epsgeo* )

28.46.2.12 **bool** Go::SurfaceTools::getSfAdjacencyInfo ( *shared\_ptr*< **ParamSurface** > *sf1*, *shared\_ptr*< **CurveOnSurface** > *sf\_cv1*, *shared\_ptr*< **ParamSurface** > *sf2*, *shared\_ptr*< **CurveOnSurface** > *sf\_cv2*, **double** *tol*, *int* & *bd1*, *int* & *bd2*, **bool** & *same\_orient* )

Given two neighbouring surfaces, *sf1* and *sf2*, and information about the common boundary, fetch information about the adjacency configuration

#### Parameters

|               |                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| <i>sf1</i>    | one surface                                                                                                       |
| <i>sf_cv1</i> | the boundary curve/trimming curve corresponding to <i>sf1</i> at the boundary common with <i>sf2</i>              |
| <i>sf2</i>    | the other surface                                                                                                 |
| <i>sf_cv2</i> | the boundary curve/trimming curve corresponding to <i>sf2</i> at the boundary common with <i>sf1</i>              |
| <i>tol</i>    | adjacency tolerance                                                                                               |
| <i>return</i> | parameter true if the two surfaces share the same boundary and that boundary is boundary trimmed in both surfaces |

## Parameters

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>bd1</i>         | boundary curve of first surface which follows the common boundary, -1=no such boundary curve, 0=umin, 1=umax, 2=vmin, 3=vmax |
| <i>bd2</i>         | boundary curve of second surface which follows the common boundary                                                           |
| <i>same_orient</i> | whether or not the surface boundaries have got the same orientation along the common boundary                                |

**28.46.2.13** void Go::SurfaceTools::iterateCornerPos ( Point & *vertex*, std::vector< std::pair< shared\_ptr< ParamSurface >, Point > > *sfs*, double *tol* )

Compute the corner where a number of surfaces meet. This function is relevant if the surfaces almost interpolate the same corner. If the surface is elementary (cone, sphere, ...), then this surface has more influence on the corner position than spline surfaces.

## Parameters

|               |                                                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vertex</i> | the position of the corner. This point is moved during the computation to get closer to a point shared by all surfaces                                                                                                                                                                            |
| <i>sfs</i>    | the surfaces meeting in this corner and the surface parameter associated with the corner. Note that the parameter does not necessarily lie at a corner of the underlying non-trimmed surface and it might also represent a vertex in a surface model and may lie internally at a surface boundary |

**28.46.2.14** CurveLoop Go::SurfaceTools::outerBoundarySfLoop ( shared\_ptr< ParamSurface > *surf*, double *degenerate\_epsilon* )

Fetch the outer boundary loop of a parametric surface.

**28.46.2.15** void Go::SurfaceTools::parameterizeByBaseSurf ( const ParamSurface & *sf*, const std::vector< double > & *points*, std::vector< double > & *parvals* )

Parameterize a point set by projecting the points onto a given base surface

**28.46.2.16** void Go::SurfaceTools::surface\_seedfind ( const Point & *pt*, const ParamSurface & *sf*, const RectDomain \* *rd*, double & *u*, double & *v* )

Estimate a start point to a closest point iteration between a given point, *pt*, and a given surface, *sf*, possibly restricted to the parameter domain *rd*.

**28.46.2.17** void GO\_API Go::SurfaceTools::surfaceClosed ( const Go::SplineSurface & *sf*, bool & *closed\_dir\_u*, bool & *closed\_dir\_v*, double *closed\_tol* = 1e-06 )

Check if the surface is closed in one or both parameter directions

## 28.47 Go::TesselatorUtils Namespace Reference

Related to the relative resolution of tessellation.

### Functions

- void [getResolution](#) (const [ParamSurface](#) \*surf, int &u\_nmb, int &v\_nmb, int uv\_nmb=400)
- [shared\\_ptr](#)<[LineCloud](#)> [getCtrPol](#) ([GeomObject](#) \*obj)  
*Fetch the control polygon of some geometric entity.*

### 28.47.1 Detailed Description

Related to the relative resolution of tessellation.

### 28.47.2 Function Documentation

28.47.2.1 [shared\\_ptr](#)<[LineCloud](#)> [Go::TesselatorUtils::getCtrPol](#) ( [GeomObject](#) \* obj )

Fetch the control polygon of some geometric entity.

28.47.2.2 void [Go::TesselatorUtils::getResolution](#) ( const [ParamSurface](#) \* surf, int & u\_nmb, int & v\_nmb, int uv\_nmb = 400 )

Get the mesh size of a surface in the two parameter directions given the total number of nodes in the mesh. NB! u\_nmb\*v\_nmb are probably not exactly equal to uv\_nmb

## 28.48 Go::tpUtils Namespace Reference

### Functions

- [template](#)<class [edgeType](#)>  
void [adjacentEdges](#) ([edgeType](#) \*edge, [bool](#) at\_start\_of\_edge, [std::vector](#)< [edgeType](#) \* > &adjacent, [std::vector](#)< [bool](#) > &at\_start)
- [template](#)<class [edgeType](#)>

*Return continuity between end of edge1 and start of edge2.*

### 28.48.1 Function Documentation

28.48.1.1 [template](#)<class [edgeType](#)> void [Go::tpUtils::adjacentEdges](#) ( [edgeType](#) \* edge, [bool](#) at\_start\_of\_edge, [std::vector](#)< [edgeType](#) \* > & adjacent, [std::vector](#)< [bool](#) > & at\_start )

Consider the 'node' or 'corner' implied by the startpoint (if at\_start\_of\_edge is true) or endpoint (if it is false). The vector adjacent is filled with all edges with that 'node' as a startpoint (indicated by a true at the corresponding place in the at\_start vector) or endpoint (false in at\_start). The edge originally asked for is not included.

Definition at line 60 of file tpUtils.h.

28.48.1.2 `template<class edgeType > tpJointType Go::tpUtils::checkContinuity ( const edgeType * edge1, const edgeType * edge2, double neighbour, double gap, double bend, double kink )`

Return continuity between end of edge1 and start of edge2.

Definition at line 138 of file tpUtils.h.

## 28.49 Go::Utils Namespace Reference

## 28.50 Go::VolumeInterpolator Namespace Reference

This namespace contains functions used to interpolate a set of points.

### Functions

- [SplineVolume](#) \* [regularInterpolation](#) ([const BsplineBasis](#) &basis\_u, [const BsplineBasis](#) &basis\_v, [const BsplineBasis](#) &basis\_w, [std::vector< double >](#) &par\_u, [std::vector< double >](#) &par\_v, [std::vector< double >](#) &par\_w, [std::vector< double >](#) &points, [int](#) dimension, [bool](#) rational, [std::vector< double >](#) &weights)

### 28.50.1 Detailed Description

This namespace contains functions used to interpolate a set of points.

### 28.50.2 Function Documentation

28.50.2.1 **SplineVolume\*** `Go::VolumeInterpolator::regularInterpolation ( const BsplineBasis & basis_u, const BsplineBasis & basis_v, const BsplineBasis & basis_w, std::vector< double > & par_u, std::vector< double > & par_v, std::vector< double > & par_w, std::vector< double > & points, int dimension, bool rational, std::vector< double > & weights )`

Interpolate a set of regular, parameterized interpolation points. The parameterization is assumed to correspond to the given B-spline bases (select interpolation points in the Greville points). The function throws if the input parameters are inconsistent

#### Parameters

|                  |                                                                              |
|------------------|------------------------------------------------------------------------------|
| <i>basis_u</i>   | spline basis in the first parameter direction                                |
| <i>basis_v</i>   | spline basis in the second parameter direction                               |
| <i>basis_w</i>   | spline basis in the third parameter direction                                |
| <i>par_u</i>     | parameter values in 1. parameter direction corresponding to point            |
| <i>par_v</i>     | parameter values in 2. parameter direction corresponding to point            |
| <i>par_w</i>     | parameter values in 2. parameter direction corresponding to point            |
| <i>points</i>    | the regular point set                                                        |
| <i>dimension</i> | dimension of geometry space                                                  |
| <i>rational</i>  | whether or not a rational surface is expected                                |
| <i>weights</i>   | the weights of the rational volume, used only if <code>rational==true</code> |

## 28.51 Go::VolumeModelCreator Namespace Reference

### Functions

### 28.52.1 Detailed Description

This namespace contains free functions operating on parametric volumes.

### 28.52.2 Function Documentation

**28.52.2.1** `int GO_API Go::VolumeTools::analyzePeriodicity ( const SplineVolume & sf, int direction, double knot_tol = 1e-12 )`

Analyze periodicity of volume based on number of repeating knots and control points. The return value is -1 if the volume edges are disjoint, otherwise  $k$  if  $sf$  is  $C^k$  continuous across the seam. These are sufficient but not necessary conditions for periodicity, so it is possible that a call to `analyzePeriodicityDerivs()` will yield a higher degree of periodicity. The current implementation is quite slow, and not optimized for speed.

## Parameters

|                  |                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sf</i>        | reference to the <a href="#">SplineVolume</a> to be analyzed                                                                                                 |
| <i>direction</i> | specify 'direction' to be '0' to check for periodicity in the first parameter direction, or '1' to check the second parameter direction, or 2 for the third. |
| <i>knot_tol</i>  | the tolerance used when comparing knot intervals                                                                                                             |

## Returns

-1 if the volume edges are disjoint, otherwise k if the

**28.52.2.2** `shared_ptr<SplineCurve> Go::VolumeTools::approxVolParamCurve ( shared_ptr< ParamCurve > spacecurve, shared_ptr< ParamVolume > vol, double tol, int max_iter, double & maxdist )`

**28.52.2.3** `bool Go::VolumeTools::cornerToCornerVols ( shared_ptr< ParamVolume > vol1, shared_ptr< SurfaceOnVolume > vol_sf1, shared_ptr< ParamVolume > vol2, shared_ptr< SurfaceOnVolume > vol_sf2, double tol )`

Check if two neighbouring volumes in a volume set have a corner-to-corner configuration, i.e. no T-joints

## Parameters

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <i>vol1</i>    | one volume                                                               |
| <i>vol_sf1</i> | the boundary face corresponding to vol1 at the boundary common with vol2 |
| <i>vol2</i>    | the other volume                                                         |
| <i>vol_sf1</i> | the boundary face corresponding to vol2 at the boundary common with vol1 |
| <i>return</i>  | parameter true of the configuration is corner-to-corner                  |

**28.52.2.4** `shared_ptr<SurfaceOnVolume> Go::VolumeTools::getBoundarySurface ( shared_ptr< SplineVolume > vol, int idx )`

Given a spline volume, fetch all boundary surfaces.

**28.52.2.5** `std::vector<shared_ptr<ParamSurface>> Go::VolumeTools::getBoundarySurfaces ( shared_ptr< ParamVolume > vol )`

Given a parametric volume, fetch all boundary surfaces.

**28.52.2.6** `bool Go::VolumeTools::getCorrCoefVolEnum ( shared_ptr< SplineVolume > vol1, shared_ptr< SplineVolume > vol2, int bd1, int bd2, int orientation, bool same_seq, std::vector< std::pair< int, int > > & enumeration )`

Given information about the adjacency relationship between two spline volumes (the enumeration of the common boundary and the correspondance in parameterization, see the function `getVolAdjacencyInfo`), fetch the enumeration of pairwise corresponding coefficients. The function returns false if the spline spaces of the two surfaces at the common boundary are not the same.

28.52.2.7 `shared_ptr<SurfaceOnVolume> Go::VolumeTools::getOrientedBoundarySurface ( shared_ptr<SplineVolume > vol, int idx )`

Given a spline volume, fetch all boundary surfaces and ensure a consistent normal vector direction of these surfaces

28.52.2.8 `std::vector<shared_ptr<ParamSurface> > Go::VolumeTools::getOrientedBoundarySurfaces ( shared_ptr<ParamVolume > vol )`

Given a parametric volume, fetch all boundary surfaces and ensure a consistent normal vector direction of these surfaces

28.52.2.9 `bool Go::VolumeTools::getVolAdjacencyInfo ( shared_ptr< ParamVolume > vol1, shared_ptr< SurfaceOnVolume > vol_sf1, shared_ptr< ParamVolume > vol2, shared_ptr< SurfaceOnVolume > vol_sf2, double tol, int & bd1, int & bd2, int & orientation, bool & same_seq )`

Given two neighbouring volumes, vol1 and vol2, and information about the common boundary, fetch information about the adjacency configuration

#### Parameters

|                    |                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vol1</i>        | the first volume                                                                                                                                                                                                                                                                                  |
| <i>vol_sf1</i>     | the boundary surface/trimming surface corresponding to vol1 at the boundary common with vol2                                                                                                                                                                                                      |
| <i>vol2</i>        | the other volume                                                                                                                                                                                                                                                                                  |
| <i>vol_sf2</i>     | the boundary surface/trimming surface corresponding to vol2 at the boundary common with vol1                                                                                                                                                                                                      |
| <i>tol</i>         | adjacency tolerance                                                                                                                                                                                                                                                                               |
| <i>return</i>      | parameter true if the two volumes share the same boundary and that boundary is boundary trimmed in both volumes                                                                                                                                                                                   |
| <i>bd1</i>         | boundary surface of first volume which follows the common boundary, -1=no such boundary surface, 0=umin, 1=umax, 2=vmin, 3=vmax, 4=wmin, 5=wmax                                                                                                                                                   |
| <i>bd2</i>         | boundary surface of second volume which follows the common boundary                                                                                                                                                                                                                               |
| <i>orientation</i> | =0: The surfaces at the common boundary have the same orientation in both parameter directions, =1: the orientation is opposite in the first parameter direction, =2: the orientation is opposite in the second parameter direction, =3: the orientation is opposite in both parameter directions |
| <i>same_seq</i>    | tells if 1. parameter direction of the first boundary surface corresponds to the 1. parameter direction of the second boundary surface (true) or if the parameter directions are swapped (false)                                                                                                  |

28.52.2.10 `bool Go::VolumeTools::getVolBdCoefEnumeration ( shared_ptr< SplineVolume > vol, int bd, int bd_cv, std::vector< int > & enumeration )`

Given a spline volume, a boundary surface enumeration (bd=0:umin, bd=1:umax, bd=2:vmin, bd=3:vmax, bd=4:wmin, bd=5:wmax) and a boundary curve enumeration corresponding to the boundary surface (bd\_cv=0:umin, bd\_cv=1:umax, bd\_cv=2:vmin, bd\_cv=3:vmax), fetch the enumeration of the volume coefficients along that boundary curve

28.52.2.11 `bool Go::VolumeTools::getVolCoefEnumeration ( shared_ptr< SplineVolume > vol, int bd, std::vector< int > & enumeration )`

Given a spline volume and a boundary enumeration (bd=0:umin, bd=1:umax, bd=2:vmin, bd=3:vmax, bd=4:wmin, bd=5:wmax), fetch the enumeration of the volume coefficients at that boundary surface

28.52.2.12 `bool Go::VolumeTools::getVolCoefEnumeration ( shared_ptr< SplineVolume > vol, int bd, std::vector< int > & enumeration_bd, std::vector< int > & enumeration_bd2 )`

Given a spline volume and a boundary enumeration (bd=0:umin, bd=1:umax, bd=2:vmin, bd=3:vmax, bd=4:wmin, bd=5:wmax), fetch the enumeration of the volume coefficients at that boundary surface

28.52.2.13 `shared_ptr< SplineCurve > Go::VolumeTools::liftVolParamCurve ( shared_ptr< ParamCurve > pcurve, shared_ptr< ParamVolume > vol, double tol )`

Approximate a parameter curve in the parameter space of a given volume by a space curve

28.52.2.14 `shared_ptr< SplineCurve > Go::VolumeTools::projectVolParamCurve ( shared_ptr< ParamCurve > spacecurve, shared_ptr< ParamVolume > vol, double tol )`

Approximate a given space curve by a curve in the parameter space of a given volume

28.52.2.15 `shared_ptr< SplineVolume > Go::VolumeTools::representCurveAsVolume ( const SplineCurve & curve, int cv_dir, const BsplineBasis & other_bas1, const BsplineBasis & other_bas2, bool rational )`

Describe a curve as a lower-dimensional volume in a given direction.

#### Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>curve</i>      | the curve that we want to express as a volume                                                                                                                                                                                                                                                                                                                         |
| <i>cv_dir</i>     | If this variable is set to 0, then the curve's parameter will become the <i>first</i> parameter in the generated volume. If it is set to 1, the curve's parameter will become the <i>second</i> parameter in the generated volume. If it is set to 2, the curve's parameter will become the <i>third</i> parameter in the generated volume. Other values are illegal. |
| <i>other_bas1</i> | the first <a href="#">BsplineBasis</a> for the additional parameter directions. If <i>cv_dir</i> is 0, this will be the second parameter direction on the volume. Otherwise, it will be the first parameter direction                                                                                                                                                 |
| <i>other_bas2</i> | the second <a href="#">BsplineBasis</a> for the additional parameter directions. If <i>cv_dir</i> is 2, this will be the second parameter direction on the volume. Otherwise, it will be the third parameter direction                                                                                                                                                |
| <i>rational</i>   | define whether the generated volume shall be specified as <i>rational</i> or not.                                                                                                                                                                                                                                                                                     |

#### Returns

a shared pointer to a new [SplineVolume](#), expressing the curve in a space of lower dimensionality.

28.52.2.16 `shared_ptr< SplineVolume > Go::VolumeTools::representSurfaceAsVolume ( const SplineSurface & surface, int sf_dir1, int sf_dir2, const BsplineBasis & other_bas, bool rational )`

Describe a surface as a lower-dimensional volume in given directions.

## Parameters

|                  |                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>surface</i>   | the surface that we want to express as a volume                                                                                                                                                 |
| <i>sf_dir1</i>   | The volume parameter direction from the first surface parameter direction. The value of <i>sf_dir1</i> must be either 0, 1 or 2. Other values are illegal.                                      |
| <i>sf_dir2</i>   | The volume parameter direction from the second surface parameter direction. The value of <i>sf_dir2</i> must be either 0, 1 or 2, and different from <i>sf_dir1</i> . Other values are illegal. |
| <i>other_bas</i> | the <a href="#">BsplineBasis</a> for the additional volume parameter direction, different <i>sf_dir1</i> and <i>sf_dir2</i> .                                                                   |
| <i>rational</i>  | define whether the generated volume shall be specified as <i>rational</i> or not.                                                                                                               |

## Returns

a shared pointer to a new [SplineVolume](#), expressing the surface in a space of lower dimensionality.

**28.52.2.17** `shared_ptr<SplineCurve> Go::VolumeTools::representVolumeAsCurve ( const SplineVolume & volume, int cv_dir )`

Describe a volume as a high-dimensional curve in a given direction. If the volume is rational, the curve will be non-rational and living in the homogenous space.

## Parameters

|               |                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>volume</i> | the volume to express as a curve                                                                                                                                                                                                                                                                                                                            |
| <i>cv_dir</i> | the parameter direction that will be kept when defining the curve (the other two will disappear, as the control points in this direction will be lumped together and expressed as single control points in a higher-dimensional space. ' <i>cv_dir</i> ' takes the values 0, 1 or 2 for keeping the first, second or third parameter direction respectively |

## Returns

shared pointer to a new [SplineCurve](#), expressing the volume as a curve in a high-dimensional space.

**28.52.2.18** `shared_ptr<SplineSurface> Go::VolumeTools::representVolumeAsSurface ( const SplineVolume & volume, int sf_dir1, int sf_dir2 )`

Describe a volume as a high-dimensional surface in two given directions. If the volume is rational, the surface will be non-rational and living in the homogenous space.

## Parameters

|                |                                                                                                                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>volume</i>  | the volume to express as a surface                                                                                                                                                                                                                                                                                               |
| <i>sf_dir1</i> | the volume parameter direction to become the first parameter direction of the surface, either 0, 1 or 2.                                                                                                                                                                                                                         |
| <i>sf_dir2</i> | the volume parameter direction to become the second parameter direction of the surface, either 0, 1 or 2, and different from <i>sf_dir1</i> . The control points in the direction different from <i>sf_dir1</i> and <i>sf_dir2</i> will be lumped together and expressed as single control points in a higher-dimensional space. |

## Returns

shared pointer to a new [SplineSurface](#), expressing the volume as a surface in a high-dimensional space.

```
28.52.2.19 void Go::VolumeTools::volCommonSplineSpace (shared_ptr< SplineVolume > vol1, int bd1, shared_ptr< SplineVolume > vol2, int bd2, int orientation, bool same_seq)
```

Given two spline volumes sharing a common boundary and information about the configuration of this boundary in the spline volumes (see the explanation of `getVolAdjacencyInfo`), ensure that the two volumes share the same spline space at the common boundary

`void swapEdgesAwayFromInteriorNode (DartType &dart, ListType &swapped_edges)`
- `template<class TraitsType , class DartType , class ListType >`  
`void swapEdgesAwayFromBoundaryNode (DartType &dart, ListType &swapped_edges)`
- `template<class TraitsType , class DartType , class DartListType >`  
`void swapEdgeInList (const typename DartListType::iterator &it, DartListType &elist)`

### Constrained (Delaunay) Triangulation

- `template<class TraitsType , class DartType >`  
`DartType insertConstraint (DartType &dstart, DartType &dend, bool optimize_delaunay)`

## 28.59.1 Detailed Description

Main interface to TTL.

This namespace contains the basic generic algorithms for the TTL, the Triangulation Template Library. Examples of functionality are:

- Incremental Delaunay triangulation
- Constrained triangulation
- Insert/remove nodes and constrained edges
- Traversal operations
- Misc. queries for extracting information for visualisation systems etc.

#### General requirements and assumptions:

- *DartType* and *TraitsType* should be implemented in accordance with the description in [Application Programming Interface to TTL \(API\)](#).
- A "**Requires:**" section in the documentation of a function template shows which functionality is required in *TraitsType* to support that specific function. Functionality required in *DartType* is the same (almost) for all function templates; see [Application Programming Interface to TTL \(API\)](#) and the example referred to.
- When a reference to a *dart* object is passed to a function in TTL, it is assumed that it is oriented *counterclockwise* (CCW) in a triangle unless it is explicitly mentioned that it can also be *clockwise* (CW). The same applies for a dart that is passed from a function in TTL to the users *TraitsType* class (or struct).
- When an edge (represented with a dart) is swapped, it is assumed that darts outside the quadrilateral where the edge is a diagonal are not affected by the swap. Thus, [TraitsType::swapEdge](#) must be implemented in accordance with this rule.

## Glossary:

- General terms are explained in [Application Programming Interface to TTL \(API\)](#).
- *CCW* - counterclockwise
- *CW* - clockwise
- *0\_orbit*, *1\_orbit* and *2\_orbit*: A sequence of darts around a node, around an edge and in a triangle respectively; see [ttl::get\\_0\\_orbit\\_interior](#) and [ttl::get\\_0\\_orbit\\_boundary](#)
- *arc* - In a triangulation an arc is equivalent with an edge

## See also

## 28.59.2 Function Documentation

28.59.2.1 `template<class TraitsType , class DartType > bool ttl::convexBoundary ( const DartType & dart )`

Checks if the boundary of a triangulation is convex.

## Parameters

|             |                                                 |
|-------------|-------------------------------------------------|
| <i>dart</i> | A CCW dart at the boundary of the triangulation |
|-------------|-------------------------------------------------|

- [TraitsType::crossProduct2d](#) (const Dart&, const Dart&)

Definition at line 1368 of file `ttl.h`.

28.59.2.2 `template<class TraitsType , class DartType > bool ttl::degenerateTriangle ( const DartType & dart )`

Definition at line 1262 of file `ttl.h`.

28.59.2.3 `template<class DartType , class DartListType > void ttl::get_0_orbit_boundary ( const DartType & dart, DartListType & orbit )`

Gets the 0-orbit around a node at the boundary

## Parameters

|             |                                                                                         |
|-------------|-----------------------------------------------------------------------------------------|
| <i>dart</i> | A dart (CCW or CW) positioned at a <i>boundary node</i> and at a <i>boundary edge</i> . |
|-------------|-----------------------------------------------------------------------------------------|

## Return values

|              |                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>orbit</i> | Sequence of darts with one orbit for each arc. All the darts, <i>except the last</i> one, have the same orientation (CCW or CW) as <i>dart</i> , and <i>dart</i> is the first element in the sequence. |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- `DartListType::push_back (DartType&)`

## Note

- The last dart in the sequence have opposite orientation compared to the others!

```
28.59.2.4 template<class DartType , class DartListType > void ttl::get_0_orbit_interior (const DartType & dart, DartListType & orbit)
```

Gets the 0-orbit around an interior node.

## Parameters

|             |                                                           |
|-------------|-----------------------------------------------------------|
| <i>dart</i> | A dart (CCW or CW) positioned at an <i>interior</i> node. |
|-------------|-----------------------------------------------------------|

## Return values

|              |                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>orbit</i> | Sequence of darts with one orbit for each arc. All the darts have the same orientation (CCW or CW) as <i>dart</i> , and <i>dart</i> is the first element in the sequence. |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- `DartListType::push_back (DartType&)`

```

Definition at line 844 of file `ttl.h`.

28.59.2.6 `template<class DartType , class DartListType > void tti::getBoundary ( const DartType & dart, DartListType & boundary )`

Gets the boundary as sequence of darts, where the edges associated with the darts are boundary edges, given a dart with an associating edge at the boundary of a topology structure. The first dart in the sequence will be the given one, and the others will have the same orientation (CCW or CW) as the first. Assumes that the given dart is at the boundary.

#### Parameters

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <i>dart</i>     | A dart at the boundary (CCW or CW)                                     |
| <i>boundary</i> | A sequence of darts, where the associated edges are the boundary edges |

- `DartListType::push_back (DartType&)`

Definition at line 889 of file tti.h.

28.59.2.7 `template<class DartType > int tti::getDegreeOfNode ( const DartType & dart )`

Returns the degree of the node associated with *dart*.

#### Definition:

The *degree* (or valency) of a node *V* in a triangulation, is defined as the number of edges incident with *V*, i.e., the number of edges joining *V* with another node in the triangulation.

Definition at line 1012 of file tti.h.

28.59.2.8 `template<class DartType > void tti::getNeighborNodes ( const DartType & dart, std::list< DartType > & node_list, bool & boundary )`

Definition at line 1072 of file tti.h.

28.59.2.9 `template<class TraitsType , class DartType > DartType tti::insertConstraint ( DartType & dstart, DartType & dend, bool optimize_delaunay )`

Inserts a constrained edge between two existing nodes in a triangulation. If the constraint falls on one or more existing nodes and this is detected by the predicate `TraitsType::orient2d`, which should return zero in this case, the constraint is split. Otherwise a degenerate triangle will be made along the constraint.

#### Parameters

|                          |                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dstart</i>            | A CCW dart with the start node of the constraint as the source node                                                                                                                                                              |
| <i>dend</i>              | A CCW dart with the end node of the constraint as the source node                                                                                                                                                                |
| <i>optimize_delaunay</i> | If set to <code>true</code> , the resulting triangulation will be a <i>constrained Delaunay triangulation</i> . If set to <code>false</code> , the resulting triangulation will not necessarily be of constrained Delaunay type. |

## Return values

|                 |                                           |
|-----------------|-------------------------------------------|
| <i>DartType</i> | A dart representing the constrained edge. |
|-----------------|-------------------------------------------|

- [TraitsType::orient2d](#) (DartType&, DartType&, PointType&)
- [TraitsType::swapEdge](#) (DartType&)
- [ttl::optimizeDelaunay](#) if *optimize\_delaunay* is set to `true`

## Assumes:

- The constrained edge must be inside the existing triangulation (and it cannot cross the boundary of the triangulation).

Definition at line 556 of file `ttl_constr.h`.

```
28.59.2.10 template<class TraitsType , class DartType , class PointType > bool ttl::insertNode (DartType & dart, PointType & point)
```

Inserts a new node in an existing Delaunay triangulation and swaps edges to obtain a new Delaunay triangulation. This is the basic function for incremental Delaunay triangulation. When starting from a set of points, an initial Delaunay triangulation can be created as two triangles forming a rectangle that contains all the points. After `insertNode` has been called repeatedly with all the points, [ttl::removeRectangularBoundary](#) can be called to remove triangles at the boundary of the triangulation so that the boundary form the convex hull of the points.

Note that this incremental scheme will run much faster if the points have been sorted lexicographically on *x* and *y*.

## Parameters

|              |                                                                                            |
|--------------|--------------------------------------------------------------------------------------------|
| <i>dart</i>  | An arbitrary CCW dart in the tringulation.<br>Output: A CCW dart incident to the new node. |
| <i>point</i> | A point (node) to be inserted in the triangulation.                                        |

## Return values

|             |                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bool</i> | <code>true</code> if <i>point</i> was inserted; <code>false</code> if not.<br>If <i>point</i> is outside the triangulation, or the input dart is not valid, <code>false</code> is returned. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- [TraitsType::splitTriangle](#) (DartType&, const PointType&)
- [ttl::locateTriangle](#)
- [ttl::recSwapDelaunay](#)

## Note

- For efficiency reasons *dart* should be close to the insertion *point*.

Definition at line 530 of file ttl.h.

**28.59.2.18** `template<class TraitsType , class PointType , class DartType > bool ttl::locateFaceSimplest ( const PointType & point, DartType & dart )`

Locates the face containing a given point. It is assumed that the tessellation (e.g. a triangulation) is *regular* in the sense that there are no holes, the boundary is convex and there are no degenerate faces.

Parameters

|              |                                                                                      |
|--------------|--------------------------------------------------------------------------------------|
| <i>point</i> | A point to be located                                                                |
| <i>dart</i>  | An arbitrary CCW dart in the triangulation<br>Output: A CCW dart in the located face |

Return values

|             |                                        |
|-------------|----------------------------------------|
| <i>bool</i> | true if a face is found; false if not. |
|-------------|----------------------------------------|

- [TraitsType::orient2d](#) (DartType&, DartType&, PointType&)

#### Note

- If `false` is returned, *point* may still be inside a face if the tessellation is not *regular* as explained above.

Locates the triangle containing a given point. It is assumed that the triangulation is *regular* in the sense that there are no holes and the boundary is convex. This function deals with degeneracy to some extent, but round-off errors may still lead to a wrong result if triangles are degenerate.

#### Parameters

|              |                                                                                          |
|--------------|------------------------------------------------------------------------------------------|
| <i>point</i> | A point to be located                                                                    |
| <i>dart</i>  | An arbitrary CCW dart in the triangulation<br>Output: A CCW dart in the located triangle |

#### Return values

|             |                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bool</i> | <code>true</code> if a triangle is found; <code>false</code> if not.<br>If <i>point</i> is outside the triangulation, in which case <code>false</code> is returned, then the edge associated with <i>dart</i> will be at the boundary of the triangulation. |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- [ttl::locateFaceSimplest](#)
- [ttl::inTriangle](#)

Definition at line 667 of file `ttl.h`.

**28.59.2.21** `template<class TraitsType , class DartType , class DartListType > void ttl::optimizeDelaunay ( DartListType & elist )`

Optimizes the edges in the given sequence according to the *Delaunay* criterion, i.e., such that the edge will fulfill the *circumcircle* criterion (or equivalently the *MaxMin* angle criterion) with respect to the quadrilaterals where they are diagonals.

## Parameters

|              |                       |
|--------------|-----------------------|
| <i>elist</i> | The sequence of edges |
|--------------|-----------------------|

- [TraitsType::swapEdge](#) (DartType& *dart*)  
**Note:** Must be implemented such that *dart* is delivered back in a position as seen if it was glued to the edge when swapping (rotating) the edge CCW
- [ttl::swapTestDelaunay](#)

Definition at line 1434 of file ttl.h.

```
28.59.2.22 template<class TraitsType , class DartType , class DartListType > void ttl::optimizeDelaunay (DartListType & elist,
 const typename DartListType::iterator end)
```

Definition at line 1441 of file ttl.h.

```
28.59.2.23 template<class DartType > void ttl::positionAtNextBoundaryEdge (DartType & dart)
```

Given a *dart*, CCW or CW, positioned in a 0-orbit at the boundary of a tessellation. Position *dart* at a boundary edge in the same 0-orbit.

If the given *dart* is CCW, *dart* is positioned at the left boundary edge and will be CW.

If the given *dart* is CW, *dart* is positioned at the right boundary edge and will be CCW.

## Note

- The given *dart* must have a source node at the boundary, otherwise an infinit loop occurs.

Definition at line 1343 of file ttl.h.

```
28.59.2.24 template<class TraitsType , class DartType > void ttl::recSwapDelaunay (DartType & diagonal)
```

Recursively swaps edges in the triangulation according to the *Delaunay* criterion.

## Parameters

|                 |                                                                   |
|-----------------|-------------------------------------------------------------------|
| <i>diagonal</i> | A CCW dart representing the edge where the recursion starts from. |
|-----------------|-------------------------------------------------------------------|

- [TraitsType::swapEdge](#) (DartType&)  
**Note:** Must be implemented such that the darts outside the quadrilateral are not affected by the swap.
- Calls itself recursively

Definition at line 1630 of file ttl.h.

28.59.2.25 `template<class TraitsType , class DartType > void ttl::removeBoundaryNode ( DartType & dart )`

Removes the boundary node associated with *dart* and updates the triangulation to be Delaunay.

- [ttl::swapEdgesAwayFromBoundaryNode](#)
- [ttl::optimizeDelaunay](#)
- [TraitsType::removeBoundaryTriangle](#) (Dart&)

Definition at line 415 of file `ttl.h`.

28.59.2.26 `template<class TraitsType , class DartType > void ttl::removeInteriorNode ( DartType & dart )`

Removes the interior node associated with *dart* and updates the triangulation to be Delaunay.

- [ttl::swapEdgesAwayFromInteriorNode](#)
- [ttl::optimizeDelaunay](#)
- [TraitsType::reverse\\_splitTriangle](#) (Dart&)

#### Note

- The node cannot belong to a fixed (constrained) edge that is not swappable. (An endless loop is likely to occur in this case).

Definition at line 479 of file `ttl.h`.

28.59.2.27 `template<class TraitsType , class DartType > void ttl::removeNode ( DartType & dart )`

Removes the node associated with *dart* and updates the triangulation to be Delaunay.

- [ttl::removeBoundaryNode](#) if *dart* represents a node at the boundary
- [ttl::removeInteriorNode](#) if *dart* represents an interior node

#### Note

- The node cannot belong to a fixed (constrained) edge that is not swappable. (An endless loop is likely to occur in this case).

Definition at line 394 of file `ttl.h`.

28.59.2.28 `template<class TraitsType , class DartType > void ttl::removeRectangularBoundary ( DartType & dart )`

Removes the rectangular boundary of a triangulation as a final step of an incremental Delaunay triangulation. The four nodes at the corners will be removed and the resulting triangulation will have a convex boundary and be Delaunay.

## Parameters

|             |                                                                                           |
|-------------|-------------------------------------------------------------------------------------------|
| <i>dart</i> | A CCW dart at the boundary of the triangulation<br>Output: A CCW dart at the new boundary |
|-------------|-------------------------------------------------------------------------------------------|

- [ttl::removeBoundaryNode](#)

## Note

- This function requires that the boundary of the triangulation is a rectangle with four nodes (one in each corner).

Definition at line 365 of file ttl.h.

**28.59.2.29** `template<class DartType > bool ttl::same_0_orbit ( const DartType & d1, const DartType & d2 )`

Checks if the two darts belong to the same 0-orbit, i.e., if they share a node. *d1* and/or *d2* can be CCW or CW.

(This function also examines if the the node associated with *d1* is at the boundary, which slows down the function (slightly). If it is known that the node associated with *d1* is an interior node and a faster version is needed, the user should implement his/her own version.)

Definition at line 1198 of file ttl.h.

**28.59.2.30** `template<class DartType > bool ttl::same_1_orbit ( const DartType & d1, const DartType & d2 )`

Checks if the two darts belong to the same 1-orbit, i.e., if they share an edge. *d1* and/or *d2* can be CCW or CW.

Definition at line 1232 of file ttl.h.

**28.59.2.31** `template<class DartType > bool ttl::same_2_orbit ( const DartType & d1, const DartType & d2 )`

Checks if the two darts belong to the same 2-orbit, i.e., if they lie in the same triangle. *d1* and/or *d2* can be CCW or CW

Definition at line 1248 of file ttl.h.

**28.59.2.32** `template<class TraitsType , class DartType , class DartListType > void ttl::swapEdgeInList ( const typename DartListType::iterator & it, DartListType & elist )`

Swap the the edge associated with iterator *it* and update affected darts in *elist* accordingly. The darts affected by the swap are those in the same quadrilateral. Thus, if one want to preserve one or more of these darts on should keep them in *elist*.

Definition at line 1842 of file ttl.h.

**28.59.2.33** `template<class TraitsType , class DartType , class ListType > void ttl::swapEdgesAwayFromBoundaryNode ( DartType & dart, ListType & swapped_edges )`

Swaps edges away from the (boundary) node associated with *dart* in such a way that when removing the edges that remain incident with the node, the boundary of the triangulation will be convex. This function is used as a first step in [ttl::removeBoundaryNode](#)

## Return values

|             |                                   |
|-------------|-----------------------------------|
| <i>dart</i> | A CCW dart incident with the node |
|-------------|-----------------------------------|

- [TraitsType::swapEdge](#) (DartType& *dart*)
